

Seminar notes on ALGEBRA

Gau Syu

Last Update: May 4, 2014

Preface

This is a collection of notes for our seminar on Algebra.

At first, it was designed as a collection of solutions to Serge Lang's *Algebra*, i.e. [Lan02]. However, it doesn't cover solutions of all exercises, but some interesting topics.

In addition to these exercises, I try to introduce some related concepts and conclusions. Furthermore, I add some notes for a inofficial seminar after school whose theme is to learn some systematic knowledge about algebra.

After one year of march, abandoning step-by-step biting, we start a series of seminar on interesting topics. Thus, this book become far from an exercise solution.

Based on this reason, I rearrange this book and rename it as *Seminar notes on Algebra*.

The main reference material is still Serge Lang's *Algebra*. Besides, some related books and articles, especially *Wikipedia*, give great help.

Thanks to all.

Gau Syu

Part I

Mathematical Structures

The notion of “Mathematical structure”, as an explicit mathematical concept, first appears in N.Bourbaki’s *Elements of Mathematics*, Volume 1 *Theory of Sets*, Chapter 4 “Structures”. By using axiomatic set theory, Bourbaki suggested a general definition of “mathematical structure” and “isomorphism”, although this theory was rarely used even in his own book.

Category Theory, as newborn fundamental theory, provides a more suitable language to describe mathematical structures and influence modern mathematics and other subjects profoundly. Hence more and more modern algebra textbooks involve an introduction to category theory.

In this part, we introduce some knowledge of category theory we will mention in the rest of this book. Most of them can be found in every textbook of category theory.

The standard reference is MacLane’s famous *Categories for the Working Mathematician* [Lan98]. In addition, F.W.Lawvere and S.H.Schanuel’s *Conceptual Mathematics* [LS97], S.Awodey’s *Category Theory* [Awo10] are straightaway textbooks. F.Borceux *Handbook of categorical algebra* [Bor08] is an informative Encyclopedia.

Although unnecessary in principle, having basic algebraic training is helpful to understand this part. One can refer R.Godement’s *Cours d’algèbre* [God63], N.Jacobson’s *Basic Algebra* [Jac80], M.Artin’s *Algebra* [Art11] and even any undergraduate textbook of algebra.

Cap.1 The Language of Categories

In this chapter, we start with the basic vocabulary of categories, functors, natural transformations, monomorphisms, epimorphisms, isomorphisms. The analogies between monomorphisms and epimorphisms, covariant and contravariant functors, lead to the famous duality principle which is, with the Yoneda lemma, one of the key results of the first chapter.

§1.1 Introduction

Why category?

Many similar phenomena and constructions with similar properties occur in completely different mathematical fields. To describe precisely such phenomena and investigate such constructions simultaneously, the language of categories emerges.

For past years, categorists have developed a symbolism that allows one quickly to visualize quite complicated facts by means of diagrams.

Nowadays, category theory become a powerful language provides suitable vehicles that allow one to transport problems from one area of mathematics to another area, where solutions are sometimes easier. Therefore, the language of categories become more and more popular in modern mathematics and other fields like logic, computer science, linguistics and philosophy.

More history comment can be found in many textbooks about category theory.

What is a category?

There are several ways to define what is a category; in the usual foundations of mathematics, these two definitions are equivalent. We now provide a popular one.

Definition 1.1.1. A **category** \mathcal{C} consists of the following data:

- a collection $\text{ob } \mathcal{C}$ of **objects**.
- a collection $\text{hom } \mathcal{C}$ of **morphisms** (or **arrows**, **maps**) between objects.

Each morphism f has a unique **source** object A and **target** object B .

We write $f: A \longrightarrow B$, and say “ f is a morphism from A to B ”, “ A is the **domain** of f ” and “ B is the **codomain** of f ”.

We write $\text{Hom}(A, B)$ (or $\text{Hom}_{\mathcal{C}}(A, B)$ when there may be confusion about to which category $\text{Hom}(A, B)$ refers) to denote the collection of all morphisms from A to B . (Some authors write $\text{Mor}(A, B)$ or simply $\mathcal{C}(A, B)$ instead.)

- for every three objects A, B and C , a binary operation

$$\text{Hom}(A, B) \times \text{Hom}(B, C) \longrightarrow \text{Hom}(A, C)$$

called **composition of morphisms**.

The composition of $f: A \longrightarrow B$ and $g: B \longrightarrow C$ is written as $g \circ f$ or simply gf . (Some authors use “diagrammatic order”, writing $f; g$ or fg .)

subject to the following axioms:

associativity if $f: A \longrightarrow B, g: B \longrightarrow C$ and $h: C \longrightarrow D$ then

$$h \circ (g \circ f) = (h \circ g) \circ f$$

identity for every object A , there exists a morphism $1_A: A \longrightarrow A$ (some times write id_A) called the **identity morphism** for A , such that for every morphism $f: A \longrightarrow B$, we have $1_B \circ f = f = f \circ 1_A$.

From these axioms, one can prove that there is exactly one identity morphism for every object. Some authors use a slight variation of the definition in which each object is identified with the corresponding identity morphism.

Remark. To emphasize the category \mathcal{C} , one often say an object (resp. morphism, arrow, map) in \mathcal{C} or a \mathcal{C} -objects (resp. \mathcal{C} -morphism, \mathcal{C} -arrow, \mathcal{C} -map).

Remark. Category theory provide a framework to discuss so-called “categorical properties”. Informally, a **categorical property** is a statement about objects and arrows in a category. More technically, a category provide a two-typed first order language with objects and morphisms as distinct types, together with the relations of an object being the source or target of a morphism and a symbol for composing two morphisms, thus a category property is a statement in such a language.

Let us now define a “homomorphism of categories”.

Definition 1.1.2. A **functor** F from a category \mathcal{A} to a category \mathcal{B} consists of the following data:

- a mapping

$$\text{ob } \mathcal{A} \longrightarrow \text{ob } \mathcal{B}$$

between the collections of objects of \mathcal{A} and \mathcal{B} ; the image of $A \in \text{ob } \mathcal{A}$ is written $F(A)$ or just FA ;

- for every pair of objects A, A' of \mathcal{A} , a mapping

$$\text{Hom}_{\mathcal{A}}(A, A') \longrightarrow \text{Hom}_{\mathcal{B}}(F(A), F(A'))$$

the image of $f \in \text{Hom}_{\mathcal{A}}(A, A')$ is written $F(f)$ or just Ff .

subject to the following axioms:

- for every pair of morphisms $f \in \text{Hom}_{\mathcal{A}}(A, A'), g \in \text{Hom}_{\mathcal{A}}(A', A'')$,

$$F(g \circ f) = F(g) \circ F(f)$$

- for every object $A \in \text{ob } \mathcal{A}$,

$$F(1_A) = 1_{F(A)}$$

Given two functors $F: \mathcal{A} \rightarrow \mathcal{B}$ and $G: \mathcal{B} \rightarrow \mathcal{C}$, a pointwise composition immediately produces a new functor $G \circ F: \mathcal{A} \rightarrow \mathcal{C}$. This composition law is obviously associative.

On the other hand, every category \mathcal{C} has an identity functor, which can be simply obtained by choosing every mapping in the above definition to be the identity. It is an identity for the previous composition law.

To summarize, the relationship between categories and functors is just like the one between objects and morphisms in a category. Thus a careless argument could lead to the conclusion that categories and functors constitute a new category, which is doubtful.

Foundations and size issues

You may find that we use the undefined word “collection” instead of “set” or “class”. The chosen of the word depends on the logical foundations we chose: when we use ZFC with one universe, then we choose the word “set” and all classical mathematical objects we considered such as sets, groups etc

is small respect to the universe; when we use class theory like NBG, then we choose the word “class” and all classical mathematical objects are sets. More details can be found in the beginning of [Bor08] or section 1.8 of [Awo10].

However, the foundation of category theory is independent of the axioms of set theory. In fact, category theory can be used to provide the foundations for mathematics as an alternative to set theory. Therefore we can rewrite the sentences of our axioms about what is a category in fully formal logic, which allow us to use the undefined word “collection”. More details can be found in *nLab* or [Lan98].

Nevertheless, without set theory, the size-discussions such as “a collection of all XXX” do not make sense. Indeed, one of the lessons from the Russell’s paradox is that the unrestricted usage of quantifiers is very dangerous.

After choose an axiom system of set theory, the size issues make sense. In usual class theory such as NBG, a class is *small* means it is a set, while in ZFC with one universe, a set is *small* means it is an element of the universe.

A category \mathcal{C} is called **small** if both $\text{ob}\mathcal{C}$ and $\text{hom}\mathcal{C}$ are small, and **proper large** otherwise. A category is called **locally small** if for each pair of objects A and B , $\text{Hom}(A, B)$ is small. Many important categories in mathematics (such as the category of sets), although not small, are at least locally small. For this reason, people tend to use the word “category” instead of “locally small category”. Following this convention, we will simply put a locally small category called “category”. This does not cause ambiguity, since we will still use the word “**large category**” if needed.

Under the above agreements, one can safely claim that all small categories and functors constitute a category, which is usually denoted by **Cat**. On the other hand, the size of the “category” of all (locally small) categories and functors are larger than every large category, thus it does not exist under the usual set-theoretic axioms.

Of course, one can also choose an axiom system of set theory which promise numerous sizes rather than just two: “small” and “large”. In this case, all smaller categories and functors constitute a larger category. For instance, all locally small categories and functors form a “very large” (namely, larger than proper large categories) category, called **CAT**: see *The Joy of*

Cats i.e.[AHS09].

More details about the foundations and size issues can be found in *nLab* and related publications.

§1.2 Examples

The discussion of small categories and functors provide the first example of category in this book, i.e. **Cat**. We should introduce some other examples in this section.

In fact, traditional mathematics has provided a number of examples by different ways.

Example 1.2.1. Many traditional mathematical structures are obtained by attaching some structures on sets. They provided a lot of obvious examples of categories.

- Sets ¹ and functions: **Set**.
- Groups and group homomorphisms: **Grp**.
- Rings and ring homomorphisms: **Ring**.
- Real vector spaces and linear mappings: **Vect** _{\mathbb{R}} .
- Right R –modules and module homomorphisms: **Mod** _{R} .
- Topological spaces and continuous mappings: **Top**.
- Uniform spaces and uniformly continuous functions: **Uni**.
- Differentiable manifolds and smooth mappings: **Diff**.
- Metric spaces and metric mappings: **Met**.
- Real Banach spaces and bounded linear mappings: **Ban** _{∞} .
- Real Banach spaces and linear contractions: **Ban**.

All of these categories encapsulate one “kind of mathematical structure”. These are often called “concrete” categories (we will introduce a technical definition that these examples all satisfy later).

¹By this word we mean the small ones the set theory provided, e.g. small sets if we use ZFC with one universe. In such case, to avoid ambiguity, we use “large set” to call the general sets, which may be not small. A usual class theory already provides a word “class”, thus one can also simply assume we have chose a usual class theory as our foundational set theory.

Example 1.2.2. Some mathematical devices can also be viewed as categories.

- **Mat:** The set of natural numbers \mathbb{N} can be viewed as a category as following: choose as objects the natural numbers and as arrows from n to m the matrices with n rows and m columns; the composition is the usual product of matrices.
- Every set S can be viewed as a category whose objects are the elements of S and the only morphisms are identities.

In general, a category whose only morphisms are the identities is called a **discrete category**.

- A poset $(S, <)$ can be viewed as a category whose objects are the elements of S and the set $\text{Hom}(x, y)$ of morphisms is a singleton when $x < y$ and is empty otherwise. The possibility of defining a (unique) composition law is just the transitivity axiom of the partial order; the existence of identities is just the reflexivity axiom.
- A monoid (M, \cdot) can be seen as a category \mathcal{M} with a single object $*$ and $\text{Hom}(*, *) = M$ as a set of morphisms; the composition law is just the multiplication of the monoid.

Do not worry if some of these examples are unfamiliar to you. Later on, we will take a closer look at some of them. In addition, there are also many examples emerge from outside of mathematics, such as logic, computer science, linguistics and philosophy. Those examples can be found in [Awo10] and related publications.

Basic examples via a given category

From a given category \mathcal{C} , there are various ways to construct new categories. Here are some basic constructions.

Example 1.2.3. Any category \mathcal{C} can itself be considered as a new category in a different way: the objects are the same as those in the original category but the arrows are those of the original category reversed. This is called the **dual** or **opposite category** and is denoted by \mathcal{C}^{op} .

Obviously, the double dual category of a category is itself. The concept of dual category implies an important principle, the *duality principle*. We will see soon it in this chapter.

Example 1.2.4 (slice category). Let us fix an object $I \in \text{ob}\mathcal{C}$. The category \mathcal{C}/I of “arrows over I ” is defined by the following.

- Objects: the arrows of \mathcal{C} with codomain I .
- Morphisms from an object $(f: A \rightarrow I)$ to another $(g: B \rightarrow I)$: the morphisms $h: A \rightarrow B$ in \mathcal{C} satisfying the “commutative triangles over I ”

$$\begin{array}{ccc} A & \xrightarrow{h} & B \\ & \searrow f & \swarrow g \\ & I & \end{array}$$

i.e. $g \circ h = f$.

- The composition law is that induced by the composition of \mathcal{C} .

Remark. Notice that in the case of **Set**, a function $f: A \rightarrow I$ can be identified with the I –indexed family of sets $\{f^{-1}(i)\}_{i \in I}$ so that the previous category is just that of I –indexed families of sets and I –indexed families of functions.

Example 1.2.5 (coslice category). Again fixing an object $I \in \text{ob}\mathcal{C}$, the category I/\mathcal{C} of “arrows under I ” is defined by the following.

- Objects: the arrows of \mathcal{C} with domain I .
- Morphisms from an object $(f: I \rightarrow A)$ to another $(g: I \rightarrow B)$: the morphisms $h: A \rightarrow B$ in \mathcal{C} satisfying the “commutative triangles under I ”

$$\begin{array}{ccc} & I & \\ f \swarrow & & \searrow g \\ A & \xrightarrow{h} & B \end{array}$$

i.e. $h \circ f = g$.

- The composition law is that induced by the composition of \mathcal{C} .

Example 1.2.6. Now we consider all the arrows of \mathcal{C} . The category $\mathcal{C}^{\rightarrow}$ of all arrows is defined by the following.

- Objects: the arrows of \mathcal{C} .
- A morphism from an object $(f: A \rightarrow B)$ to another $(g: C \rightarrow D)$ is a pair $(h: A \rightarrow C, k: B \rightarrow D)$ of morphisms of \mathcal{C} satisfying a “commutative square”

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ h \downarrow & & \downarrow k \\ C & \xrightarrow{g} & D \end{array}$$

- The composition law is induced pointwise by the composition in \mathcal{C} .

The simplest examples

We now introduce some simple examples which can be inspired by the axioms of categories immediately.

Example 1.2.7. The category **0** has no objects or arrows.

The category **1** has one object and its identity arrow. It looks like

$$\bullet$$

The category **2** has two objects, their required identity arrows, and exactly one arrow between the objects. It looks like

$$\bullet \longrightarrow \bullet$$

The category **3** has three objects, their required identity arrows, exactly one arrow from the first to the second object, exactly one arrow from the second to the third object, and exactly one arrow from the first to the third object (which is therefore the composite of the other two). It looks like

$$\begin{array}{ccc} \bullet & \longrightarrow & \bullet \\ & \searrow & \downarrow \\ & & \bullet \end{array}$$

One can see these categories look like quivers. Indeed, a category can be viewed a quiver with extra structure. More details can be found in *nLab*.

The notation **1, 2, 3** comes from the fact that these categories are in fact the ordinals regarded as posets and thus categories. We will discuss this in the later part.

§1.3 Monic-, epi- and isomorphisms

The basic notions about functions are injectivity, surjectivity and bijectivity. To generalize them to the context of category theory, one need characterize them without using elements. Early category theorists believed that the cancellation properties provide the correct generalization, thus they define the following notions.

Definition 1.3.1. A morphism f is called **monic**, or a **monomorphism**, if it is left cancellable, that means for any morphisms

$$\cdot \xrightarrow[\beta]{\alpha} \cdot \xrightarrow{f} \cdot$$

$f\alpha = f\beta$ implies $\alpha = \beta$.

Dually, f is called **epi**, or an **epimorphism**, if it is right cancellable, that means for any morphisms

$$\cdot \xrightarrow{f} \cdot \xrightarrow[\beta]{\alpha} \cdot$$

$\alpha f = \beta f$ implies $\alpha = \beta$.

The followings are the basic propositions about monomorphisms and epimorphisms.

Proposition 1.3.2. *every identity morphism is both monic and epi. The composite of two monomorphisms (resp. epimorphisms) is also a monomorphism (resp. epimorphism).*

Proposition 1.3.3 (Triangle lemma). *If the composite $g \circ f$ of two morphisms is monic, then so is f ; if the composite is epi, then so is g .*

By the definition, a morphism is monic means it is left cancellable, but this does not implies the existence of its left inverse. For epimorphisms, the argument is similar.

Definition 1.3.4. Consider two morphisms $f: A \rightarrow B$ and $g: B \rightarrow A$ in a category. When $g \circ f = 1_A$, f is called a **section** of g , g is called a **retraction** of f and A is called a **retract** of B .

Proposition 1.3.5. *In a category, every section is a monomorphism and every retraction is an epimorphism.*

Definition 1.3.6. A morphism $f: A \rightarrow B$ is called a **split monomorphism**, if it has a retraction. Dually, f is called a **split epimorphism**, if it has a section. If f is both split monic and split epi, then we say it is an **isomorphism** and A is **isomorphic** to B , denoted by $A \approx B$.

Remark. It is clear that any split monomorphism must be monic and any split epimorphism is epi, hence any isomorphism is both monic and epi. However, the converses are not true in general case.

A morphism which is both monic and epi is traditionally called a **bimorphism**, although this is a bad name cause confusions when we go to higher category theory. A category in which every bimorphism is an isomorphism is called **balanced**.

Examples

Example 1.3.7. In **Set**, **Grp**, **Mod_R** or **Top**, monomorphisms (resp. epimorphisms) are precisely those morphisms that have injective (resp. surjective) underlying functions. The verifications will be given in corresponding chapters.

Example 1.3.8. In **Ring**, monomorphisms are precisely those morphisms that have injective underlying functions. However, epimorphisms are not necessarily surjective. For instance, the inclusion map $\mathbb{Z} \hookrightarrow \mathbb{Q}$ is a non-surjective epimorphism. To see this, note that any ring homomorphism on \mathbb{Q} is determined entirely by its action on \mathbb{Z} . A similar argument shows that the canonical ring homomorphism from any commutative ring R to any one of its localizations is an epimorphism.

Example 1.3.9. In the category **DivAb** of divisible abelian groups and group homomorphisms between them, there are monomorphisms that are not injective: consider, for example, the quotient map $q: \mathbb{Q} \rightarrow \mathbb{Q}/\mathbb{Z}$ from additive group of rational numbers. This is obviously not an injective map. Nevertheless, it is a monomorphism in this category. Indeed, choose G a divisible abelian group and $f, g: G \rightarrow \mathbb{Q}$ two group homomorphisms such

that $q \circ f = q \circ g$ Putting $h = f - g$ we have $q \circ h = 0$ and the thesis becomes $h = 0$. Given an element $x \in G$, $h(x)$ is an integer since $q \circ h = 0$. If $h(x) \neq 0$, then one can easily find a contradiction.

Example 1.3.10. In the category of connected pointed topological spaces and pointed continue maps, every coverings map are monomorphisms although they are usually not injective. This is just the unique lifting property of covering maps, one can find it in a textbook about algebraic topology, for example, [Hat02].

Example 1.3.11. In **Set**, **Grp**, **Mod_R**, isomorphisms are precisely those morphisms that have bijective underlying functions. In **Top**, isomorphisms are exactly the homeomorphisms. Unfortunately, a continuous bijection is in general not a homeomorphism. For instance, the map from the half-open interval $[0, 1)$ to the unit circle S^1 (thought as a subspace of the complex plane) which sends x to $e^{2\pi xi}$ is continuous and bijective but not a homeomorphism since the inverse map is not continuous at 1.

The counter-examples above shows that the notions of monomorphism and epimorphism do not meet the original requirements, thus category theorists develop some variations to fix this. One can find them in *nLab* or *The Joy of Cats* .

§1.4 Natural transformations

Just as the study of groups is not complete without a study of homomorphisms, so the study of categories is not complete without the study of functors. However, the study of functors is itself not complete without the study of the morphisms between them: the natural transformations.

Definition 1.4.1. Consider two functors F, G from a category \mathcal{A} to \mathcal{B} . A **natural transformation** $\alpha: F \Rightarrow G$ from F to G is a family of morphisms

$$(\alpha_A: F(A) \longrightarrow G(A))_{A \in \text{ob } \mathcal{A}}$$

of \mathcal{B} indexed by the objects in \mathcal{A} satisfying the following commutative diagrams for every morphism $f: A \rightarrow A'$ in \mathcal{A}

$$\begin{array}{ccc} F(A) & \xrightarrow{\alpha_A} & G(A) \\ F(f) \downarrow & & \downarrow G(f) \\ F(A') & \xrightarrow{\alpha_{A'}} & G(A') \end{array}$$

i.e. $\alpha_{A'} \circ F(f) = G(f) \circ \alpha_A$.

Let F, G, H be functors from \mathcal{A} to \mathcal{B} and $\alpha: F \Rightarrow G, \beta: G \Rightarrow H$ be natural transformations. Then the formula

$$(\beta \circ \alpha)_A = \beta_A \circ \alpha_A$$

defines a new natural transformation $\beta \circ \alpha: F \Rightarrow H$.

This composition law is clearly associative and possesses identity for each functor. Thus, a careless argument would deduce the existence of a category whose objects are the functors from \mathcal{A} to \mathcal{B} and whose morphisms are the natural transformations between them. Such a category is called the **functor category** from \mathcal{A} to \mathcal{B} and usually denoted by $[\mathcal{A}, \mathcal{B}]$ or $\mathcal{B}^{\mathcal{A}}$.

Remark. We say this argument is careless since there is a size issue:

If \mathcal{A} and \mathcal{B} are *small*, then $[\mathcal{A}, \mathcal{B}]$ is also *small*.

If \mathcal{A} is *small* and \mathcal{B} is *locally small*, then $[\mathcal{A}, \mathcal{B}]$ is still *locally small*.

Even if \mathcal{A} and \mathcal{B} are *locally small*, if \mathcal{A} is not *small*, then $[\mathcal{A}, \mathcal{B}]$ will usually not be *locally small*.

As a partial converse to the above, if \mathcal{A} and $[\mathcal{A}, \mathbf{Set}]$ are *locally small*, then \mathcal{A} must be *essentially small*: see Freyd & Street (1995).

In the above discussion, we have used a first composition law for natural transformations. In fact, there exists another possible type of composition for natural transformations.

Proposition 1.4.2. *Consider the following situation:*

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{F} & \mathcal{B} & \xrightarrow{F'} & \mathcal{C} \\ & \Downarrow \alpha & & \Downarrow \beta & \\ & G & & G' & \end{array}$$

Where $\mathcal{A}, \mathcal{B}, \mathcal{C}$ are categories, F, G, F', G' are functors and α, β are natural transformations.

First, we have the composite functors $F'F$ and $G'G$ and a commutative square for every object $A \in \text{ob } \mathcal{A}$:

$$\begin{array}{ccc} F'F(A) & \xrightarrow{F'(\alpha_A)} & F'G(A) \\ \beta_{F(A)} \downarrow & & \downarrow \beta_{G(A)} \\ G'F(A) & \xrightarrow{G'(\alpha_A)} & G'G(A) \end{array}$$

Now define $(\beta * \alpha)_A$ to be the diagonal of this square, i.e.

$$(\beta * \alpha)_A = \beta_{G(A)} \circ F'(\alpha_A) = G'(\alpha_A) \circ \beta_{F(A)}$$

Then $\beta * \alpha$ is also a natural transformation, called the **Godement product** of α and β .

Use the naturalities and functorialities, one can easily check this proposition and also the following.

Proposition 1.4.3 (Interchange law). *Consider this situation*

$$\begin{array}{ccccc} & \curvearrowright & & \curvearrowright & \\ & \Downarrow \alpha & & \Downarrow \alpha' & \\ \mathcal{A} & \xrightarrow{\quad} & \mathcal{B} & \xrightarrow{\quad} & \mathcal{C} \\ & \Downarrow \beta & & \Downarrow \beta' & \\ & \curvearrowleft & & \curvearrowleft & \end{array}$$

Where $\mathcal{A}, \mathcal{B}, \mathcal{C}$ are categories and $\alpha, \beta, \alpha', \beta'$ are natural transformations. Then the following equality holds:

$$(\beta' \circ \alpha') * (\beta \circ \alpha) = (\beta' * \beta) \circ (\alpha' * \alpha)$$

For the sake of brevity and with the notations of the previous propositions, we shall often write $\beta * F$ instead of $\beta * 1_F$ or $G * \alpha$ instead of $1_G * \alpha$.

Remarks on naturality

You may have seen the word “*natural*” on different occasions. But what does this word mean? Intuitively, it makes reference to a description which is independent of any choices.

Category theory offer a formal definition.

Recall such a word usually occurs in a situation where something be transformed into another. To say this process is *natural*, in the sense of category theory, means it can be realized by a *natural transformation*.

For instance, the term “naturally isomorphic” can be formalized by

Definition 1.4.4. Let α be a natural transformation between two functors F and G from the category \mathcal{A} to \mathcal{B} . If, for every object A in \mathcal{A} , the morphism α_A is an isomorphism in \mathcal{B} , then α is said to be a **natural isomorphism**, and F and G are said to be **naturally isomorphic**, denoted by $F \cong G$.

Example 1.4.5 (Opposite group). Statements such as

“Every group is *naturally isomorphic* to its opposite group”

abound in modern mathematics.

What the above statement really means is:

“The identity functor $\mathbf{I}: \mathbf{Grp} \rightarrow \mathbf{Grp}$ is *naturally isomorphic* to the opposite functor $\text{op}: \mathbf{Grp} \rightarrow \mathbf{Grp}$.”

Such a translation also automatically provide a proof to the original statement.

Example 1.4.6 (Double dual). Let k be a field, then for every vector space V over k we have a “natural” injective linear map $V \rightarrow V^{**}$ from V into its double dual. These maps are “natural” in the following sense: the double dual operation is a functor, and the maps are the components of a natural transformation from the identity functor to the double dual functor.

However, “unnatural” isomorphisms also abound in traditional mathematics.

Example 1.4.7 (Dual of finite-dimensional vector spaces). Origin: *Wikipedia*
Revised by: *MathOverflow*

Every finite-dimensional vector space is isomorphic to its dual space, but this isomorphism is not natural.

One reason, which is given by *Wikipedia*, is that this isomorphism relies on an arbitrary choice of isomorphism. However, this is a completely different matter and has nothing to do with naturality: the linear dual is a contravariant functor while the identity functor on $\mathbf{FinVect}_k$ is covariant, thus there is no possibility to compare them via a natural transformation.

A more acceptable reason comes from a poset in *MathOverflow*. Dan Petersen pointed that if we just consider the category of finite-dimensional vector spaces and linear isomorphisms, temporarily denote it by \mathcal{C} . Then there are two obvious functors $\mathcal{C} \rightarrow \mathcal{C}^{\text{op}}$: the linear dual, and the natural isomorphism $\mathcal{C} \rightarrow \mathcal{C}^{\text{op}}$ maps each linear isomorphism to its inverse. These functors are **unnaturally isomorphic**.

However, take as objects finite-dimensional vector spaces with a nondegenerate bilinear form and maps linear transforms that respect the bilinear form. Then the resulting category has a natural isomorphism from the linear dual to the identity.

To formalize the ideal that some isomorphisms are not natural, one can introduce the notion of **infranatural transformation**, which is just a family of morphisms indexed by the objects in the source category. Thus an **unnatural isomorphism** is just an infranatural isomorphism which is not natural.

Example 1.4.8. Quote from *MathOverflow*

Take \mathcal{C} to be the category with one object and two morphisms. Then the identity functor is **unnaturally isomorphic** to the functor that sends both morphisms to the identity map.

In practice, a particular map between individual objects is said to be a **natural isomorphism**, meaning implicitly that it is actually defined on the entire category, and defines a natural transformation of functors, otherwise, an **unnatural isomorphism**.

Remark. Some authors distinguish notations, using \cong for natural isomorphisms and \approx for isomorphisms may not be natural, reserving $=$ for equalities.

The examples in *Wikipedia* may not fit, since what they compared are in fact functors with different domains. Some right counterexamples can be found in this poset in *MathOverflow*.

§1.5 Contravariant functors

Sometimes, we will consider a mapping between categories which reverse the arrows, for instance, the inverse image mapping of functions. Such kind of mappings are essentially functors from the dual of the ordinary category, while people used to image them as “functors” from the ordinary one for brevity. For this reason, categorists introduce the concept of contravariant functors.

Definition 1.5.1. Let \mathcal{A}, \mathcal{B} be two categories, a **contravariant functor** from \mathcal{A} to \mathcal{B} is a functor from \mathcal{A}^{op} to \mathcal{B} .

Ordinary functors are also called **covariant functor** in order to distinguish them from *contravariant* ones.

Example 1.5.2. A contravariant functor from a category \mathcal{C} to **Set** is traditionally called a **presheaf** on \mathcal{C} . The category of presheaves on \mathcal{C} is denoted by $\mathbf{PSh}(\mathcal{C})$. More generally, it is frequently to call a contravariant functor from \mathcal{C} to \mathcal{D} a \mathcal{D} -valued presheaf on \mathcal{C} .

Remark. For the reason of size issue, people often require the domain of a presheaf to be small.

One define the natural transformations between contravariant functors similarly as the covariant case.

Definition 1.5.3. Consider two contravariant functors F, G from a category \mathcal{A} to a category \mathcal{B} . A **natural transformation** $\alpha: F \Rightarrow G$ from F to G is a family of morphisms

$$(\alpha_A: F(A) \longrightarrow G(A))_{A \in \text{ob } \mathcal{A}}$$

of \mathcal{B} indexed by the objects in \mathcal{A} satisfying the following commutative diagrams for every morphism $f: A \rightarrow A'$ in \mathcal{A}

$$\begin{array}{ccc} F(A) & \xrightarrow{\alpha_A} & G(A) \\ F(f) \uparrow & & \uparrow G(f) \\ F(A') & \xrightarrow{\alpha_{A'}} & G(A') \end{array}$$

i.e. $\alpha_A \circ F(f) = G(f) \circ \alpha_{A'}$.

All results about functors can be transported to the contravariant case. One can easily check that, or just apply the duality principle to obtain this transposition.

The similar idea that take both the dual of source and target categories provides the following notion.

Definition 1.5.4. Every functor $F: \mathcal{A} \longrightarrow \mathcal{B}$ induces the **opposite functor** $F^{\text{op}}: \mathcal{A}^{\text{op}} \longrightarrow \mathcal{B}^{\text{op}}$ maps objects and morphisms identically to F .

Although F^{op} works as F , it can be distinguished from F since \mathcal{A}^{op} does not coincide as \mathcal{A} as categories and similarly for \mathcal{B}^{op} . The motivation to define opposite functor is similar as opposite ring, it inverse the order of composition law.

Examples of functors

Here is some simple examples of functors and contravariant functors.

Example 1.5.5. Every category \mathcal{C} has an identity functor $\mathbf{I}_{\mathcal{C}}$ as its identity under the composition of functors.

Example 1.5.6. For any “concrete” category, for instance **Grp**, there is a functor from it to **Set**, called the **forgetful functor**: it maps a group G to the underlying set G and a homomorphism f to the corresponding function f . We will introduce the technical definition of concrete category and the forgetful functor later.

Example 1.5.7. The *power-set functor* $\mathcal{P}: \mathbf{Set} \rightarrow \mathbf{Set}$ from the category of sets to itself is obtained by mapping a set S to its power set $\mathcal{P}(S)$ and a function $f: A \rightarrow B$ to the “direct image mapping” from $\mathcal{P}(A)$ to $\mathcal{P}(B)$.

Its duality, the *contravariant power-set functor* \mathcal{Q} maps a set S to its power set $\mathcal{P}(S)$ and a function $f: A \rightarrow B$ to the “inverse image mapping”:

$$\begin{aligned} \mathcal{P}(B) &\longrightarrow \mathcal{P}(A) \\ U &\longmapsto f^{-1}(U) \end{aligned}$$

Example 1.5.8. The functor $\Delta_B: \mathcal{A} \longrightarrow \mathcal{B}$ which maps every object of \mathcal{A} to a fixed object B in \mathcal{B} and every morphism in \mathcal{A} to the identity morphism on B is called a **constant functor** or **selection functor** to B .

Example 1.5.9. The **diagonal functor** Δ is defined as the functor from \mathcal{B} to the functor category $[\mathcal{A}, \mathcal{B}]$ which sends each object B in \mathcal{B} to the constant functor to B .

Example 1.5.10. $\text{Hom}(-, -)$ can itself be viewed as two functors:

Fix an object A in \mathcal{C} , then $X \mapsto \text{Hom}(A, X)$ defined a functor from \mathcal{C} to **Set** which maps a morphism $f: X \rightarrow Y$ to the mapping

$$\begin{aligned} f_*: \text{Hom}(A, X) &\longrightarrow \text{Hom}(A, Y) \\ \phi &\longmapsto f \circ \phi \end{aligned}$$

Fix an object B in \mathcal{C} , then $X \mapsto \text{Hom}(X, B)$ defined a contravariant functor from \mathcal{C} to **Set** which maps a morphism $f: X \rightarrow Y$ to the mapping

$$\begin{aligned} f^*: \text{Hom}(Y, B) &\longrightarrow \text{Hom}(X, B) \\ \phi &\longmapsto \phi \circ f \end{aligned}$$

Moreover, one can prove that, for every morphisms $A \rightarrow B$ and $C \rightarrow D$ in \mathcal{C} , the following diagram is commutative:

$$\begin{array}{ccc} \text{Hom}(A, C) & \longrightarrow & \text{Hom}(A, D) \\ \uparrow & & \uparrow \\ \text{Hom}(B, C) & \longrightarrow & \text{Hom}(B, D) \end{array}$$

§1.6 Full and faithful functors

One may find that a “concrete” category seems can be included in **Set** via the forgetful functor. But such a “inclusion” is not like coincide those in usual sense because it is not usually injective. For instance, there are in general many different group structures on a same set. In fact, such a functor is what we call “faithful functor”.

Definition 1.6.1. A Functor $F: \mathcal{A} \rightarrow \mathcal{B}$ is said to be

1. **faithful** (resp. **full**, resp. **fully faithful**) if for any $X, Y \in \text{ob } \mathcal{A}$, the map $\text{Hom}_{\mathcal{A}}(X, Y) \rightarrow \text{Hom}_{\mathcal{B}}(F(X), F(Y))$ is injective (resp. surjective, resp. bijective).
2. **essentially surjective** if for each $B \in \text{ob } \mathcal{B}$, there exists $A \in \text{ob } \mathcal{A}$ and an isomorphism $F(A) \approx B$.

Remark. A faithful functor need not to be injective on objects or morphisms. That is, two objects X and X' may map to the same object in \mathcal{B} (which is why the range of a fully faithful functor is not necessarily equivalent to \mathcal{A}), and two morphisms $f: X \rightarrow Y$ and $f': X' \rightarrow Y'$ (with different domains and codomains) may map to the same morphism in \mathcal{B} .

Likewise, a full functor need not be surjective on objects or morphisms. There may be objects in \mathcal{B} not of the form $F(A)$ for some A in \mathcal{A} . Morphisms between such objects clearly cannot come from morphisms in \mathcal{A} .

However, we have

Proposition 1.6.2. *A functor is injective on morphisms if and only if it is faithful and injective on objects. Such a functor is called an **embedding**.*

The basic facts about the above notions are the following

Proposition 1.6.3. *Let $F: \mathcal{A} \rightarrow \mathcal{B}$ and $G: \mathcal{B} \rightarrow \mathcal{C}$ be functors.*

1. *If F and G are both isomorphisms (resp. embeddings, faithful, or full), then so is $G \circ F$.*
2. *If $G \circ F$ is an embedding (resp. faithful), then so is F .*

3. If F is essentially surjective and $G \circ F$ is full, then G is full.

Proof. 1 is obvious. Apply the triangle lemma to hom-sets, we get 2.

Under the condition of 3, each object B in \mathcal{B} is isomorphic to some $F(A)$ for $A \in \text{ob } \mathcal{A}$. Thus a morphism $h: G(B) \rightarrow G(B')$ in \mathcal{C} is isomorphic to a morphism $h': GF(A) \approx G(B) \rightarrow G(B') \approx GF(A')$. By the fullness of $G \circ F$, $h' = GF(f)$ for some morphism $f: A \rightarrow A'$ in \mathcal{A} , thus we get a morphism $g: B \rightarrow B'$ such that $G(g) = h$. \square

Full functors and faithful functors have good properties.

Proposition 1.6.4. *Let $F: \mathcal{A} \rightarrow \mathcal{B}$ be a faithful functor, then*

1. *it **reflects monomorphisms**. That is, for every morphism f in \mathcal{A} , $F(f)$ is monic implies f is monic.*
2. *it **reflects epimorphism**. That is, for every morphism f in \mathcal{A} , $F(f)$ is epi implies f is epi.*
3. *if it is also full, then it **reflects isomorphisms**.*

Proof. Let $F(f)$ be monic, then for every morphisms g, h such that $f \circ g = f \circ h$, we have $F(f) \circ F(g) = F(f) \circ F(h)$, thus $F(g) = F(h)$. Since F is faithful, $g = h$. The proof of 2 is similar.

Let $F(f)$ be an isomorphism with inverse g . Since F is full, $g = F(h)$ for some \mathcal{A} -morphism h . Then h is the inverse of f since F is faithful. \square

Corollary 1.6.5. *A fully faithful functor $F: \mathcal{A} \rightarrow \mathcal{B}$ is necessarily injective on objects up to isomorphism. That is, every objects A, A' in \mathcal{A} which are mapped to isomorphic objects in \mathcal{B} must be isomorphic.*

One can easily check that every functor $F: \mathcal{A} \rightarrow \mathcal{B}$ must **preserve isomorphisms**, that is, for every isomorphism f in \mathcal{A} , $F(f)$ is an isomorphism. However, the conditions to preserve monomorphisms and epimorphisms are much stronger. In fact, even fully faithful functors can not promise this. But if we assume F to be both fully faithful and essentially surjective, one can verify it do preserve monomorphisms and epimorphisms.

Definition 1.6.6. A functor is said to be a **weak equivalence**, if it is fully faithful and essentially surjective.

In fact, weak equivalence preserves and reflects more than just those properties mentioned above, by suitable assumptions on foundations, it keeps every interesting categorical properties, thus plays an important role in modern mathematics.

Equivalence of categories

To characterize the concept that two categories share the same properties, the most natural way is consider the isomorphisms in **Cat** (or **CAT**, more generally). Thus, we define

Definition 1.6.7. Two categories \mathcal{A} and \mathcal{B} are said to be **isomorphic**, if there exists two functors $F: \mathcal{A} \rightarrow \mathcal{B}$ and $G: \mathcal{B} \rightarrow \mathcal{A}$ which are mutually inverse to each other.

One can easily check that the inverse of an isomorphism F must be unique, thus usually denoted by F^{-1} .

Proposition 1.6.8. *A functor is an isomorphism if and only if it is full, faithful, and bijective on objects.*

Example 1.6.9. The basic fact in the representation theory of finite groups is that the category of linear representations of a finite group is isomorphic to the category of left modules over the corresponding group algebra.

However, such example is rare since the condition to be isomorphic is too strong to be satisfied in practice. A more pragmatic notion is the equivalence of categories.

Definition 1.6.10. Two categories \mathcal{A} and \mathcal{B} are said to be **equivalent**, if there exists a pair of functors $F: \mathcal{A} \rightarrow \mathcal{B}$ and $G: \mathcal{B} \rightarrow \mathcal{A}$ such that there are natural isomorphisms $F \circ G \cong \mathbf{I}_{\mathcal{B}}$ and $\mathbf{I}_{\mathcal{A}} \cong G \circ F$. In this case, we say F is an **equivalence** from \mathcal{A} to \mathcal{B} with a **weak inverse** G .

Remark. Knowledge of an equivalence is usually not enough to reconstruct its weak inverse and the natural isomorphisms: there may be many choices. (see examples below)

Remark. There is no standard notation of equivalentness, $\mathcal{A} \equiv \mathcal{B}$ and $\mathcal{A} \simeq \mathcal{B}$ are frequently used.

The most obvious relationship between equivalence and weak equivalence is the following.

Proposition 1.6.11. *An equivalence must be a weak equivalence.*

Proof. Let $F: \mathcal{A} \rightarrow \mathcal{B}$ be an equivalence with a weak inverse G and two natural isomorphism $\mathbf{I}_{\mathcal{A}} \xrightarrow{\alpha} G \circ F, F \circ G \xrightarrow{\beta} \mathbf{I}_{\mathcal{B}}$. The essential surjectivity follows from β , full faithfulness follows from α . \square

Before going forward, we prove some basic properties of weak equivalences.

Proposition 1.6.12. *If $F: \mathcal{A} \rightarrow \mathcal{B}$ and $G: \mathcal{B} \rightarrow \mathcal{C}$ are weak equivalences, then so is $G \circ F$.*

Proof. The fullness and faithfulness follows from Proposition 1.6.3. The essential surjectivity is easy to check. \square

Assuming the axiom of choice true, we have

Proposition 1.6.13. *$F: \mathcal{A} \rightarrow \mathcal{B}$ is an equivalence if and only if it is a weak equivalence.*

Proof. Let $F: \mathcal{A} \rightarrow \mathcal{B}$ be a weak equivalence, then we constitute a weak inverse $G: \mathcal{B} \rightarrow \mathcal{A}$ as following.

For each \mathcal{B} -object B , CHOICE an \mathcal{A} -object A such that $F(A) \approx B$, set $G(B) = A$. For each \mathcal{B} -morphism $f: B \rightarrow B'$, set $G(f)$ to be the inverse image of following composition

$$FG(B) \approx B \xrightarrow{f} B' \approx FG(B')$$

in \mathcal{A} , the existence and uniqueness of such an inverse image comes from the fact that F is fully faithful.

$F \circ G \cong \mathbf{I}_{\mathcal{B}}$ comes from the constitution above. To see $\mathbf{I}_{\mathcal{A}} \cong G \circ F$, just notice that F reflects isomorphisms. \square

However, if we do not assume the axiom of choice, then there is a related concept weaker than equivalence.

Definition 1.6.14. Two categories \mathcal{A} and \mathcal{B} are said to be **weak equivalent**, if there exist a category \mathcal{C} and two weak equivalence $F: \mathcal{C} \rightarrow \mathcal{A}$ and $G: \mathcal{C} \rightarrow \mathcal{B}$.

Examples

Example 1.6.15. The basic fact in the linear algebra is that **Mat** is equivalent to the category **FinVect** of finite-dimensional vector spaces and linear mappings. However, they are not isomorphic.

Example 1.6.16. Let \mathcal{C} a category with two object A, B , and four morphisms: two are the identities $1_A, 1_B$, two are isomorphisms $f: A \rightarrow B$, $g: B \rightarrow A$. Then \mathcal{C} is equivalent to **1** through the functor which maps every objects in \mathcal{C} to \bullet , and every morphisms in \mathcal{C} to the identity. However, there are two weak inverse: one maps \bullet to A and the other to B .

Example 1.6.17. Consider a category \mathcal{C} with one object X , and two morphisms $1_X, f: X \rightarrow X$, where $f \circ f = 1_X$. Of course, \mathcal{C} is equivalent to itself and $1_{\mathcal{C}}$ is an equivalence. However, there are two natural isomorphisms: one induced from 1_X and the other from f . This example shows that even the weak inverse is unique, the choices of natural isomorphisms may not.

§1.7 Subcategories

Like subsets, subgroups and so on, we now introduce the notion of subcategories in the similar way.

Definition 1.7.1. A **subcategory** of \mathcal{C} is a category whose objects and morphisms form subcollections of \mathcal{C} 's respectively.

The definition of subcategory implicit a functor which works as an inclusion on the collections of objects and morphisms, named the **inclusion functor**.

There are two different notions formalize the idea that a subcategory which is big enough to reveal the entire category.

Definition 1.7.2. If the inclusion functor is full, then we say the subcategory is **full**. If the inclusion functor is surjective on objects, then we say the subcategory is **wide** (or **lluf**).

It is obvious that the inclusion functor is necessarily an embedding. Conversely, just as subsets of a set S can be identified with isomorphism classes of injective functions into S , subcategories of a category \mathcal{C} can be identified with isomorphism classes of monic functors into \mathcal{C} . A functor is easily verified to be monic (in **Cat**, or **CAT** more generally) if and only if it is an embedding.

Consequently, inclusions are (up to isomorphism) precisely the embeddings.

Proposition 1.7.3. *A functor $F: \mathcal{A} \rightarrow \mathcal{B}$ is a (full) embedding if and only if it factors through a (full) subcategory \mathcal{C} of \mathcal{B} by an isomorphism $G: \mathcal{A} \rightarrow \mathcal{C}$ and an inclusion $E: \mathcal{C} \rightarrow \mathcal{B}$. That is $F = E \circ G$.*

Proof. Set \mathcal{C} to be the image of \mathcal{A} in \mathcal{B} . □

Moreover, inclusions are (up to (weak) equivalence) precisely the faithful functors.

Proposition 1.7.4. *A functor $F: \mathcal{A} \rightarrow \mathcal{B}$ is faithful if and only if it factors through an inclusion $E_1: \mathcal{A} \rightarrow \mathcal{C}$, a weak equivalence $G: \mathcal{C} \rightarrow \mathcal{D}$, and an inclusion $E_2: \mathcal{D} \rightarrow \mathcal{B}$. That is $F = E_2 \circ G \circ E_1$.*

Proof. Set \mathcal{D} to be the full subcategory of \mathcal{B} whose objects are same as the image of \mathcal{A} . Set \mathcal{C} to be the category whose objects are same as \mathcal{A} , while morphisms as \mathcal{D} . \square

Categories can be classified into different equivalence classes, to characterize this, we have

Definition 1.7.5. A category is said to be **skeletal** if its objects that are isomorphic are necessarily equal. Traditionally, a **skeleton** of a category \mathcal{C} is defined to be a skeletal subcategory of \mathcal{C} whose inclusion functor exhibits it as equivalent to \mathcal{C} .

Remark. However, in the absence of the axiom of choice, it is more appropriate to define a skeleton of \mathcal{C} to be any skeletal category which is weakly equivalent to \mathcal{C} .

Definition 1.7.6. A category is said to be **essentially small** if it is equivalent to a small category. Assuming the axiom of choice, this is the same as saying that it has a small skeleton.

Proposition 1.7.7. *Any two skeletons of a category are isomorphic. Conversely, two categories are equivalent if and only if they have isomorphic skeletons.*

Remark. In the absence of the axiom of choice, the term “equivalent” must be replaced by “weak equivalent”.

Terminological remark

In many fields of mathematics, objects satisfying some “universal property” are not unique on the nose, but only *unique up to unique isomorphism*. It can be tempting to suppose that in a skeletal category, where any two isomorphic objects are equal, such objects will in fact be unique on the nose. However, under the most appropriate definition of “unique” this is **not** true (in general), because of the presence of automorphisms.

More explicitly, consider the notion *cartesian product* (see Definition 2.4.1) in a category as an example. Although we colloquially speak of “a product” of objects A and B as being the object $A \times B$, strictly speaking

a product is a triple which consists of the object $A \times B$ together with the projections $A \times B \rightarrow A$ and $A \times B \rightarrow B$ which exhibit its universal property. Thus, even if the category in question is skeletal, so that there can be only one object $A \times B$ that is a product of A and B , in general this object can still “be the product of A and B ” in many different ways (in the sense that the projection maps are different): those different ways are then related by an automorphism of the object.

Finally, it is true in a few cases, though, that skeletality implies uniqueness on the nose. For instance, a *terminal object* (see Definition 2.2.1) can have no nonidentity automorphisms, so in a skeletal category, a terminal object (if one exists) really is unique on the nose.

§1.8 Comma categories

We indicate now a quite general process for constructing new categories from given ones. This type of construction will be used very often in this book.

Definition 1.8.1. Suppose that \mathcal{A} , \mathcal{B} , and \mathcal{C} are categories, and S and T (for source and target) are functors

$$\mathcal{A} \xrightarrow{S} \mathcal{C} \xleftarrow{T} \mathcal{B}$$

We can form the **comma category** $(S \downarrow T)$ as follows:

- The objects are all triples (A, f, B) with A an object in \mathcal{A} , B an object in \mathcal{B} , and $f: S(A) \rightarrow T(B)$ a morphism in \mathcal{C} .
- The morphisms from (A, f, B) to (A', f', B') are all pairs (g, h) where $g: A \rightarrow A'$ and $h: B \rightarrow B'$ are morphisms in \mathcal{A} and \mathcal{B} respectively, such that the following diagram commutes:

$$\begin{array}{ccc} S(A) & \xrightarrow{f} & T(B) \\ S(g) \downarrow & & \downarrow T(h) \\ S(A') & \xrightarrow{f'} & T(B') \end{array}$$

- Morphisms are composed by taking $(g, h) \circ (g', h')$ to be $(g \circ g', h \circ h')$, whenever the latter expression is defined.
- The identity morphism on an object (A, f, B) is $(1_A, 1_B)$.

Remark. Some people prefer the notation (S/T) rather than $(S \downarrow T)$.

The following proposition provide the “universal property” of the comma category.

Proposition 1.8.2. *For each comma category there are two canonical **forgetful functors** from it.*

- **domain functor**, $U: (S \downarrow T) \rightarrow \mathcal{A}$, which maps:
 - objects: $(A, f, B) \mapsto A$;

- *morphisms*: $(g, h) \mapsto g$;
- **codomain functor**, $V: (S \downarrow T) \longrightarrow \mathcal{B}$, which maps:
 - *objects*: $(A, f, B) \mapsto B$;
 - *morphisms*: $(g, h) \mapsto h$;

Meanwhile, there exists a natural transformation $\alpha: S \circ U \Rightarrow T \circ V$.

$$\begin{array}{ccc} (S \downarrow T) & \xrightarrow{V} & \mathcal{B} \\ U \downarrow & \alpha \nearrow & \downarrow T \\ \mathcal{A} & \xrightarrow{S} & \mathcal{C} \end{array}$$

Moreover, comma category is the universal one respect to the above property. That is, if there exist another category \mathcal{D} together with two functor $U': \mathcal{D} \rightarrow \mathcal{A}$ and $V': \mathcal{D} \rightarrow \mathcal{B}$ such that there exists a natural transformation $\alpha': S \circ U' \Rightarrow T \circ V'$.

$$\begin{array}{ccc} \mathcal{D} & \xrightarrow{V'} & \mathcal{B} \\ U' \downarrow & \alpha' \nearrow & \downarrow T \\ \mathcal{A} & \xrightarrow{S} & \mathcal{C} \end{array}$$

Then there exist a unique functor $W: \mathcal{D} \rightarrow (S \downarrow T)$ such that

$$U \circ W = U' \quad V \circ W = V' \quad \alpha * W = \alpha'.$$

Proof. The property follows just from the definition of the comma category, where the natural transformation α is defined componentwise by

$$\alpha_{(A, f, B)} = f$$

If there exist another quadruple $(\mathcal{D}, U', V', \alpha')$ satisfies the property, then we can define a functor $W: \mathcal{D} \rightarrow (S \downarrow T)$ by

$$\begin{aligned} W(D) &= (U'(D), \alpha'_D, V'(D)) \\ W(f) &= (U'(f), V'(f)) \end{aligned}$$

It is easy to check that

$$U \circ W = U' \quad V \circ W = V' \quad \alpha * W = \alpha'.$$

Conversely, the above equations enforce any functor satisfies them must be equal to W . \square

Examples

Example 1.8.3. $(\mathbf{I}_{\mathcal{C}} \downarrow \Delta_I)$, also denoted by $(\mathcal{C} \downarrow I)$ is called the **slice category** over I or *the category of objects over I* .

Example 1.8.4. $(\Delta_I \downarrow \mathbf{I}_{\mathcal{C}})$, also denoted by $(I \downarrow \mathcal{C})$ is called the **coslice category** under I or *the category of objects under I* .

Example 1.8.5. $(\mathbf{I}_{\mathcal{C}} \downarrow \mathbf{I}_{\mathcal{C}})$ is the **arrow category** $\mathcal{C}^{\rightarrow}$.

Example 1.8.6. In the case of the slice or coslice category, the identity functor may be replaced with some other functor F ; this yields a family of categories particularly useful in the study of adjoint functors. Let s, t be given object in \mathcal{C} . An object of $(s \downarrow F)$ is called a *morphism from s to F* or a **F -structured arrow** with domain s in. An object of $(F \downarrow t)$ is called a *morphism from F to t* or a **F -costructured arrow** with codomain t in.

Example 1.8.7. Let $F: \mathcal{C} \rightarrow \mathbf{Set}$ be a functor, $1: \mathbf{1} \rightarrow \mathbf{Set}$ be the functor maps the object of $\mathbf{1}$ to a singleton. The comma category $(1 \downarrow F)$ is called the **category of elements of F** , denoted by $\mathbf{Elts}(F)$. It can be explicitly described in the following way.

- Objects: the pairs (X, x) , where $X \in \text{ob } \mathcal{C}$ and $x \in F(X)$.
- Morphisms $f: (A, a) \rightarrow (B, b)$: the morphisms $f: A \rightarrow B$ in \mathcal{C} such that $F(f)(a) = b$.
- The composition law is that induced by the composition of \mathcal{C} .

The codomain functor of $\mathbf{Elts}(F)$ is also called the **forgetful functor**.

Example 1.8.8. Let $\Delta_{\mathcal{A}}$ denote the **constant functor** from \mathcal{A} to $\mathbf{1}$ and $\Delta_{\mathcal{B}}$ likewise. Then the comma category $(\Delta_{\mathcal{A}} \downarrow \Delta_{\mathcal{B}})$ is just the **product** $\mathcal{A} \times \mathcal{B}$ of \mathcal{A} and \mathcal{B} , which can be described as below.

- Objects: the pairs of objects (A, B) , where A is an object of \mathcal{A} and B of \mathcal{B} ;
- Morphisms $f: (A, B) \rightarrow (A', B')$: the pairs of arrows (a, b) , where $a: A \rightarrow A'$ is an arrow of \mathcal{A} and $b: B \rightarrow B'$ is an arrow of \mathcal{B} ;

- The composition law is the component-wise composition from the contributing categories:

$$(a', b') \circ (a, b) = (a' \circ a, b' \circ b);$$

The product $\mathcal{A} \times \mathcal{B}$ comes with two “**projection**” functors

$$p_{\mathcal{A}}: \mathcal{A} \times \mathcal{B} \longrightarrow \mathcal{A} \quad p_{\mathcal{B}}: \mathcal{A} \times \mathcal{B} \longrightarrow \mathcal{B}$$

which are defined by the formulas

$$\begin{aligned} p_{\mathcal{A}}(A, B) &= A, & p_{\mathcal{B}}(A, B) &= B, \\ p_{\mathcal{A}}(a, b) &= a, & p_{\mathcal{B}}(a, b) &= b. \end{aligned}$$

These data satisfy the following “universal property”.

Proposition 1.8.9. *Consider two categories \mathcal{A} and \mathcal{B} . For every category \mathcal{C} and every pair of functors $F: \mathcal{D} \rightarrow \mathcal{A}, G: \mathcal{D} \rightarrow \mathcal{B}$, there exists a unique functor $H: \mathcal{D} \rightarrow \mathcal{A} \times \mathcal{B}$ such that $p_{\mathcal{A}} \circ H = F, p_{\mathcal{B}} \circ H = G$.*

Proof. This follows straightly from Proposition 1.8.2. □

A point of terminology: a functor defined on the product of two categories is generally called a **bifunctor** (a functor of two “variables”). In practice, something is said to be **natural** or **functorial** in X_1, X_2, \dots implies it is actually a functor of variables X_1, X_2, \dots .

Example 1.8.10. $\text{Hom}_{\mathcal{C}}(-, -)$ is a bifunctor from $\mathcal{C}^{\text{op}} \times \mathcal{C}$ to **Set**.

§1.9 The duality principle

One may have noticed that every result proved for covariant functors has its counterpart for contravariant functors and every result proved for monomorphisms has its counterpart for epimorphisms. These facts are just special instances of a very general principle.

In the remark under Definition 1.1.1, we have shown that a category provides a two-sorted first order language and categorical properties are statements in this language.

Once we have a categorical property σ , then the dual σ^{op} can be obtained by reversing arrows and compositions. That is

1. Interchange each occurrence of “source” in σ with “target”.
2. Interchange the order of composing morphisms.

Then one can easily find that a property σ in \mathcal{C} is logical equivalent to the property σ^{op} in \mathcal{C}^{op} .

Consequently, we have

Theorem 1.9.1 (The duality principle for categories).

*Whenever a property \mathcal{P} holds for all categories,
then the property \mathcal{P}^{op} holds for all categories.*

Example 1.9.2. A morphism is monic if and only if the reverse morphism in the opposite category is epi.

§1.10 Yoneda lemma and representable functors

In this section, we will prove an important theorem. Before doing this, we give the useful concept of representable functors.

Representability is one of the most fundamental concepts of category theory, with close ties to the notion of adjoint functor and to the Yoneda lemma. It is the crucial concept underlying the idea of universal property. The concept permeates much of algebraic geometry and algebraic topology.

Definition 1.10.1. For a functor $F: \mathcal{C}^{\text{op}} \rightarrow \mathbf{Set}$ (also called a *presheaf* on \mathcal{C}), a **representative** of F is a specified natural isomorphism

$$\Phi: \text{Hom}_{\mathcal{C}}(-, X) \longrightarrow F$$

where the object X in \mathcal{C} is called a **representing object** (or **universal object**) of F .

If such a representative exists, then we say the functor F is **representable** and is **represented** by X .

Similarly, a covariant functor $F: \mathcal{C} \rightarrow \mathbf{Set}$ is said to be **representable**, if it is representable when view it as a presheaf on \mathcal{C}^{op} .

Given a category \mathcal{C} , there exists a functor:

$$\Upsilon: \mathcal{C} \longrightarrow \mathbf{PSh}(\mathcal{C})$$

sends any object $X \in \text{ob } \mathcal{C}$ to the presheaf $\text{Hom}_{\mathcal{C}}(-, X)$.

The Yoneda lemma asserts that the set of morphisms from the presheaf represented by X into any other presheaf F is in natural bijection with the set $F(X)$ that this presheaf assigns to X .

Formally:

Theorem 1.10.2 (Yoneda lemma). *There is a canonical isomorphism*

$$\text{Hom}_{\mathbf{PSh}(\mathcal{C})}(\Upsilon(X), F) \cong F(X)$$

natural in both X and F .

Remark. In some literature it is customary to denote the presheaf represented by X as h_X . In that case the above is often written

$$\text{Nat}(h_X, F) \cong F(X)$$

to emphasize that the morphisms of presheaves are natural transformations of the corresponding functors.

Proof. The crucial point is that any natural transformation

$$\alpha: \text{Hom}_{\mathcal{C}}(-, X) \Rightarrow F$$

is entirely fixed by the value $\alpha_X(1_X) \in F(X)$ of its component

$$\alpha_X: \text{Hom}(X, X) \rightarrow F(X)$$

on the identity morphism 1_X . And every such value extends to a natural transformation α .

To see this, we fix a value $\alpha_X(1_X) \in F(X)$ and consider an arbitrary object A in \mathcal{C} . If $\text{Hom}(A, X) = \emptyset$, then the component α_A must be the trivial function from empty set. If there exists a morphism $f: A \rightarrow X$, then by the naturality condition, the following commutative square has already been determined.

$$\begin{array}{ccc} \text{Hom}(X, X) & \xrightarrow{\alpha_X} & F(X) \\ f^* \downarrow & & \downarrow F(f) \\ \text{Hom}(A, X) & \xrightarrow{\alpha_A} & F(A) \end{array}$$

Consequently, all components of α have been determined.

Conversely, given a value $a = \alpha_X(1_X) \in F(X)$, define α by components as following:

$$\alpha_A(f) := F(f)(a) \quad \forall A \in \text{ob } \mathcal{C}, \forall f \in \text{Hom}(A, X)$$

It is easy to check this is a natural transformation.

The naturalities on X and F is easy to check. □

Corollaries

The Yoneda lemma has the following direct consequences. Like the Yoneda lemma, they are as easily established as they are useful and important.

Corollary 1.10.3. *The functor Υ is a full embedding.*

This Υ is customary called the **Yoneda embedding**

Proof. For any $A, B \in \text{ob } \mathcal{C}$, by the Yoneda lemma, we have

$$\text{Hom}_{\mathbf{PSh}(\mathcal{C})}(\Upsilon(A), \Upsilon(B)) \cong (\Upsilon(B))(A) = \text{Hom}_{\mathcal{C}}(A, B)$$

Thus Υ is fully faithful. The injectivity on objects is obvious. \square

Corollary 1.10.4. *For any $A, B \in \text{ob } \mathcal{C}$, we have*

$$\Upsilon(A) \cong \Upsilon(B) \iff A \cong B$$

Proof. Since Υ is fully faithful, thus reflects isomorphisms. \square

Corollary 1.10.5. *Let F be a presheaf on \mathcal{C} , then a presentation of F is uniquely determined by the universal object X together with an element $u \in F(X)$. Such a pair (X, u) satisfies the following universal property:*

For every pair (A, a) , where $A \in \text{ob } \mathcal{C}$ and $a \in F(A)$, there is a unique morphism $f: A \rightarrow X$ such that $F(f)(u) = a$.

Proof. Notice that, a presentation Φ of F is nothing but an element in the set $\text{Hom}_{\mathbf{PSh}(\mathcal{C})}(\Upsilon(X), F)$, thus by Yoneda lemma it can be corresponded to an element of $F(X)$ via Υ , say $u \in F(X)$. Then Φ is uniquely determined by X and u .

On the other hand, for each object A in \mathcal{C} , Φ_A gives a 1-1 corresponding between $\text{Hom}_{\mathcal{C}}(A, X)$ and $F(A)$, thus the universal property follows. \square

Remark. Someone may doubt the existence of the morphism in this universal property. It is possible that there is not morphisms from A to X . But in this case, Yoneda lemma ensure that $F(A)$ is empty, thus there is no pair (A, a) at all.

Remark. The $n\text{Lab}$ gives another description of this corollary: the presentation of F is the *terminal object* in the comma category $(\Upsilon \downarrow \Delta_F)$.

§1.11 Exercises

1.1. Let $f: X \rightarrow Y$ be a morphism in \mathcal{C} . Show that

1. f is monic if and only if the induced function

$$f_*: \text{Hom}(C, X) \rightarrow \text{Hom}(C, Y)$$

is injective for every object C .

2. f is epi if and only if the induced function

$$f^*: \text{Hom}(Y, C) \rightarrow \text{Hom}(X, C)$$

is injective for every object C .

3. f is split epi if and only if the induced function

$$f_*: \text{Hom}(C, X) \rightarrow \text{Hom}(C, Y)$$

is surjective for every object C .

4. f is split monic if and only if the induced function

$$f^*: \text{Hom}(Y, C) \rightarrow \text{Hom}(X, C)$$

is surjective for every object C .

1.2. Let $S, T: \mathcal{A} \rightarrow \mathcal{B}$ be two functors. Shows that there exists a 1-1 corresponding between the set of natural transformations from S to T and the set of sections of both domain functor and codomain functor.

1.3. For any categories $\mathcal{A}, \mathcal{B}, \mathcal{C}$,

1. $[\mathcal{A}, \mathcal{B}]^{\text{op}} \simeq [\mathcal{A}^{\text{op}}, \mathcal{B}^{\text{op}}]$
2. $(\mathcal{A} \times \mathcal{B})^{\mathcal{C}} \simeq \mathcal{A}^{\mathcal{C}} \times \mathcal{B}^{\mathcal{C}}$
3. $\mathcal{C}^{\mathcal{A} \times \mathcal{B}} \simeq (\mathcal{C}^{\mathcal{A}})^{\mathcal{B}} \simeq (\mathcal{C}^{\mathcal{B}})^{\mathcal{A}}$

Recall. $\mathcal{B}^{\mathcal{A}}$ is just another notation of $[\mathcal{A}, \mathcal{B}]$.

1.4. Show that the functor category $[\mathcal{A}, \mathcal{B}]$ is functorial in both \mathcal{A} and \mathcal{B} . That means, $[-, -]: \mathbf{Cat}^{\text{op}} \times \mathbf{Cat} \rightarrow \mathbf{Cat}$ is a bifunctor.

1.5. Use the duality principle to define the notion of covariant representable functor explicitly.

1.6. Show that a covariant representable functor preserves monomorphisms. On the other hand, a contravariant representable functor maps an epimorphism to a monomorphism.

1.7. Prove the covariant Yoneda lemma: There is a canonical isomorphism

$$\mathrm{Nat}(\mathrm{Hom}(X, -), F) \cong F(X)$$

natural in both X and F .

1.8. Consider the category $\mathbf{PSh}(\mathcal{C})$ of presheaves on a small category \mathcal{C} , show that a morphism in $\mathbf{PSh}(\mathcal{C})$ is monic if and only if its every component is monic. However, if we replace $\mathbf{PSh}(\mathcal{C})$ by an arbitrary functor category $[\mathcal{C}, \mathcal{D}]$, then the previous statement is no longer valid. Show this by a counterexample.

Cap.2 Theory of Limits

In this chapter, we develop a general theory about limits in categories. Cartesian product, quotient, kernel, union, intersection, and etc. are just particular cases of this theory.

§2.1 Diagrams and cones

In category theory, people often draw commutative diagrams by draw some objects connected by arrows labelled by morphisms. For instance, every kind of limit require such diagrams to define their universal property. Therefore, to give a general definition of limits, we need to formalize the concept of diagram first.

Definition 2.1.1. Let \mathcal{I} and \mathcal{C} be categories. A **diagram of shape \mathcal{I}** or a **\mathcal{I} -diagram** in \mathcal{C} is a functor $D: \mathcal{I} \rightarrow \mathcal{C}$.

Remark. The category \mathcal{I} is called the **index category** of the diagram D . If it is small, then we say the diagram is small; if it is finite (that means it has only finitely many objects and arrows), then we say the diagram is finite. For an object i in the index category, we often write D_i instead of $D(i)$.

Definition 2.1.2. A **cone** over a diagram D is an object in the comma category $(\Delta \downarrow D)$, where $\Delta: \mathcal{C} \rightarrow [\mathcal{I}, \mathcal{C}]$ is the diagonal functor. In other words, a cone over D is a natural transformation from a constant functor Δ_C to D .

More specifically, a cone over D consists of an object C in \mathcal{C} and a family of arrows in \mathcal{C} ,

$$(c_i: C \longrightarrow D_i)_{i \in \text{ob } \mathcal{I}}$$

such that for each arrow $\alpha: i \rightarrow j$ in \mathcal{I} , the following triangle commutes.

$$\begin{array}{ccc} & C & \\ c_i \swarrow & & \searrow c_j \\ D_i & \xrightarrow{D_\alpha} & D_j \end{array}$$

A morphism of cones

$$\theta: (C, c_i) \longrightarrow (C', c'_i)$$

is an arrow θ in \mathcal{C} , making each triangle

$$\begin{array}{ccc} C & \xrightarrow{\theta} & C' \\ c_i \searrow & & \swarrow c'_i \\ & D_i & \end{array}$$

commute.

Remark. We also denote the category of cones over D by $\mathbf{Cone}(D)$.

Definition 2.1.3. A **co-cone** under a diagram D is an object in the comma category $(D \downarrow \Delta)$. In other words, a co-cone under D is a natural transformation from D to a constant functor Δ_C .

More specifically, a co-cone under D consists of an object C in \mathcal{C} and a family of arrows in \mathcal{C} ,

$$(c_i: D_i \longrightarrow C)_{i \in \text{ob } \mathcal{I}}$$

such that for each arrow $\alpha: i \rightarrow j$ in \mathcal{I} , the following triangle commutes.

$$\begin{array}{ccc} D_i & \xrightarrow{D_\alpha} & D_j \\ & \searrow c_i & \swarrow c_j \\ & C & \end{array}$$

A morphism of co-cones

$$\theta: (C, c_i) \longrightarrow (C', c'_i)$$

is an arrow θ in \mathcal{C} , making each triangle

$$\begin{array}{ccc} & D_i & \\ c_i \swarrow & & \searrow c'_i \\ C & \xrightarrow{\theta} & C' \end{array}$$

commute.

Remark. We also denote the category of co-cones under D by $\mathbf{Co-cone}(D)$.

Remark. In the definition above, we mention the functor category $[\mathcal{I}, \mathcal{C}]$, which is not locally small in general and thus not a category in usual sense. To fix this, one approach is to consider small diagrams only, or at most essentially small diagrams. This works well in practice.

A more immediate approach is to notice that in the definition, we only need the category $\mathbf{Cone}(D)$ and $\mathbf{Co-cone}(D)$ to be locally small, which is always true even \mathcal{I} is not essentially small.

Commutative triangles, squares and, more generally, diagrams abound in category theory. We now give them a formal definition.

Definition 2.1.4. Let $f: A \rightarrow B$ be a morphism. If there exists an object C equipped with two morphisms $g: A \rightarrow C$ and $h: C \rightarrow B$ such that $f = h \circ g$. Then we say “ f **factors through** C by g and h ”, or simply “ f factors through C (resp. g or h)”. The triple (C, g, h) (or one of them) is called a **factorization** of f .

Definition 2.1.5. A diagram D is said to be **commutative**, if it factors through a poset. Informally, a diagram is commutative means its composition is path-independent.

Exercises

2.1. Let \mathcal{I} be one of the following categories, describe the diagrams of shape \mathcal{I} and their cones and co-cones in terms of objects and morphisms.

- **1**, which has only one object and one morphism.
- a **discrete category**, whose only morphisms are the identities.
- two parallel arrows

$$1 \begin{array}{c} \xrightarrow{\alpha} \\ \xrightarrow{\beta} \end{array} 2$$

- two convergence arrows (called a **cospan**)

$$\cdot \longrightarrow \cdot \longleftarrow \cdot$$

- two divergence arrows (called a **span**)

$$\cdot \longleftarrow \cdot \longrightarrow \cdot$$

- a **directed partially ordered set** (DPOS), which means a poset satisfies that for each two elements i, j , there exist another element $k \in I$ such that $i \leq k, j \leq k$.

For example, when $\mathcal{I} = \mathbf{0}$, the empty category, there is only one diagram of shape $\mathbf{0}$: the empty one. A cone over or a co-cone under the empty diagram is essentially just an object.

§2.2 Initial and terminal objects

Definition 2.2.1. Let \mathcal{C} be a category. An **initial object** of \mathcal{C} is an object 0 in \mathcal{C} such that for every object X in \mathcal{C} , there exists precisely one morphism $0 \rightarrow X$. Dually, an object 1 is called a **terminal object**, if for every object X in \mathcal{C} , there exists a unique morphism $X \rightarrow 1$.

Remark. It is easy to see that the initial object and terminal object are unique up to unique isomorphism.

Example 2.2.2. In the category **Set**, the empty set is the initial object and a singleton is a terminal object. The same holds in the category **Top**. Similar, the empty category **0** is the initial object in **Cat** and **1** is the terminal object.

Remark. Therefore **1** is sometimes called the **terminal category**.

Example 2.2.3. In the categories of groups, abelian groups, vector spaces, Banach spaces, and so on, $\{0\}$ is both the initial and the terminal object.

Not every category has terminal objects, for example:

Example 2.2.4. The category of infinite groups do not have a terminal object: given any infinite group G there are infinitely many morphisms $\mathbb{Z} \rightarrow G$, so G cannot be terminal.

Definition 2.2.5. If a category \mathcal{C} has a terminal object 1 , then a **global element** of another object X is a morphism $1 \rightarrow X$.

Example 2.2.6. In **Set**, global elements are just elements.

Example 2.2.7. In **Cat**, global elements are objects.

Example 2.2.8. In a slice category \mathcal{C}/I , a global element of the object $A \rightarrow I$ is just a section of it in \mathcal{C} .

§2.3 Limits and colimits

Definition 2.3.1. A **limit** of a diagram $D: \mathcal{I} \rightarrow \mathcal{C}$ is a terminal object in the comma category $\mathbf{Cone}(D)$. A **colimit** is a initial object in $\mathbf{Co-cone}(D)$.

Remark. Since the limit of a diagram D is unique up to unique isomorphism, one can just write $\varprojlim D$ for the limit without confusion.

However, it is usually helpful to indicate how the functor is evaluated on objects, in which case the limit is written in the form $\varprojlim_i D_i$.

Since a cone is not just an object (sometimes, we colloquially call it a **limit**) but together with a family of morphisms (called **projections**), thus the full formula should be like this

$$\left(p_j: \varprojlim_{i \in \text{ob } \mathcal{I}} D_i \longrightarrow D_j \right)_{j \in \text{ob } \mathcal{I}}$$

Like limit, a colimit of D can be denoted by $\varinjlim D$ for brevity, or $\varinjlim_i D_i$ if it is needed to indicate how the functor is evaluated on objects, or the full formula

$$\left(q_j: \varinjlim_{i \in \text{ob } \mathcal{I}} D_i \longleftarrow D_j \right)_{j \in \text{ob } \mathcal{I}}$$

consisting of an object (called **colimit**) and a family of morphisms (called **injections**).

Remark. In some schools of mathematics, limits are called **projective limits**, while colimits are called **inductive limits**. Also seen are (respectively) **inverse limits** and **direct limits**. Both these systems of terminology are alternatives to using “co-” when distinguishing limits and colimits.

Remark. Often, the general theory of limits (but not colimits!) works better if the functor D is taken to be contravariant. Thus, some authors define a **projective system** (or, **inverse system**) as a contravariant diagram $\mathcal{I}^{\text{op}} \rightarrow \mathcal{C}$ and an **inductive system** (or, **direct system**) as a covariant diagram $\mathcal{I} \rightarrow \mathcal{C}$.

Remark. Sometimes the term “limit” or “colimit” just refers to the vertices object in a limit cone or colimit co-cone. To emphasize this, we may call them “**limit object**” and “**colimit object**” if needed.

Here are some typical examples.

Example 2.3.2. A limit of the empty diagram is just a **terminal object**, while a colimit is just an **initial object**.

Example 2.3.3. A limit of the identity functor is just an **initial object**, while a colimit is just a **terminal object**.

Example 2.3.4. Take $\mathcal{I} = \{1, 2\}$ the discrete category with two objects and no nonidentity arrows. A diagram $D: \mathcal{I} \rightarrow \mathcal{C}$ hence is a pair of objects D_1, D_2 in \mathcal{C} . A cone over D is an object C equipped with arrows

$$D_1 \xleftarrow{c_1} C \xrightarrow{c_2} D_2$$

A co-cone under D is an object C equipped with arrows

$$D_1 \xrightarrow{c_1} C \xleftarrow{c_2} D_2$$

A limit of D is just a **product** of D_1 and D_2 in \mathcal{C} . A colimit of D is just a **coproduct** of D_1 and D_2 in \mathcal{C} .

Example 2.3.5. Take \mathcal{I} to be the following category:

$$1 \begin{array}{c} \xrightarrow{\alpha} \\ \xRightarrow{\beta} \end{array} 2$$

Hence a diagram D of shape \mathcal{I} looks like

$$D_1 \begin{array}{c} \xrightarrow{D_\alpha} \\ \xRightarrow{D_\beta} \end{array} D_2$$

A limit of D is an **equalizer** of D_α, D_β , a colimit is a **coequalizer**.

Example 2.3.6. Let (I, \leq) be a **directed set** (dpos), which means a poset satisfies that for each two elements i, j , there exist another element $k \in I$ such that $i \leq k, j \leq k$. As in Example 1.2.2, treat I as a category.

Let \mathcal{C} be a category, a projective system (inverse system) then is a set of objects $\{A_i\}_{i \in I}$ such that for each $i \leq j$, there exists a morphism $A_{i \leq j}: A_j \rightarrow A_i$ such that for any $i \leq j \leq k$, $A_{i \leq j} A_{j \leq k} = A_{i \leq k}$. A inductive system (direct system) is a set of objects $\{B_i\}_{i \in I}$ such that for each $i \leq j$, there exists a morphism $B_{i \leq j}: B_i \rightarrow B_j$ such that for any $i \leq j \leq k$, $B_{j \leq k} B_{i \leq j} = B_{i \leq k}$.

A limit of a diagram sometimes works like a monomorphism, although an individual arrow in it may not be monic.

Proposition 2.3.7. *Let $(L, \{p_i\}_{i \in \text{ob } \mathcal{I}})$ be a limit. Then two morphisms $f, g: B \rightarrow A$ are equal as long as $p_i f = p_i g$ for every $i \in \text{ob } \mathcal{I}$.*

A colimit of a diagram sometimes works like an epimorphism, although an individual arrow in it may not be epi.

Proposition 2.3.8. *Let $(C, \{q_i\}_{i \in \text{ob } \mathcal{I}})$ be a colimit. Then two morphisms $f, g: A \rightarrow B$ are equal as long as $f q_i = g q_i$ for every $i \in \text{ob } \mathcal{I}$.*

Proposition 2.3.9. *Let $F: \mathcal{I}^{\text{op}} \rightarrow \mathcal{C}$ and $G: \mathcal{J} \rightarrow \mathcal{C}$ be two diagrams and X, Y be two objects. If the limits and colimits involved exist, then we have*

$$\begin{aligned}\text{Hom}(X, \varprojlim_{\mathcal{I}^{\text{op}}} F_j) &\approx \varprojlim_{\mathcal{I}^{\text{op}}} \text{Hom}(X, F_j) \\ \text{Hom}(\varinjlim_{\mathcal{J}} G_i, Y) &\approx \varinjlim_{\mathcal{J}^{\text{op}}} \text{Hom}(G_i, Y)\end{aligned}$$

Proof. For any connection morphism $\phi_j^i: F_i \rightarrow F_j$ in the diagram F , the corresponding connection map in diagram $(\text{Hom}(X, F_i))$ is

$$\begin{aligned}\text{Hom}(X, F_i) &\rightarrow \text{Hom}(X, F_j) \\ f &\mapsto \phi_j^i \circ f\end{aligned}$$

For any connection morphism $\psi_j^i: G_i \rightarrow G_j$ in the diagram G , the corresponding connection map in diagram $(\text{Hom}(G_i, Y))$ is

$$\begin{aligned}\text{Hom}(G_j, Y) &\rightarrow \text{Hom}(G_i, Y) \\ f &\mapsto f \circ \psi_j^i\end{aligned}$$

Use these correspondings, the statements are easy to verify. \square

Exercises

2.2. Shows that a colimit of a diagram D is just the opposite of a limit of its opposite D^{op} . And use this fact to give another proof of the second statement in Proposition 2.3.9 under the assumption that the first one is true.

2.3. Describe the limits in **Set** explicitly.

2.4. In [KS06], a projective limit of a projective system $D: \mathcal{I}^{\text{op}} \rightarrow \mathcal{C}$ is defined as a representative of the representable presheaf on \mathcal{C} which maps every object X in \mathcal{C} to the limit of projective system $\text{Hom}(X, D)$ in **Set**. (Of course, if the presheaf is not representable or even not exists, then the projective limits do not exist.)

Similarly, an inductive limit of an inductive system $D': \mathcal{I} \rightarrow \mathcal{C}$ is defined as a representative of the representable functor which maps every object X in \mathcal{C} to the limit of projective system $\text{Hom}(D', X)$ in **Set**.

Shows that these definitions coincide with our definitions given in this section. A benefit of such a system of notations is that it allows us to talk about some properties of limits without assumption their existence.

2.5. Let $D: \mathcal{I} \rightarrow [\mathcal{J}, \mathcal{C}]$ be an inductive system, then, by 1.3, it can be also viewed as a functor from \mathcal{J} to $[\mathcal{I}, \mathcal{C}]$. Shows that

$$(\varinjlim_{\mathcal{I}} D)(j) \cong \varinjlim_{\mathcal{I}} (D(j)) \quad \forall j \in \text{ob } \mathcal{J}$$

i.e. the functor $\varinjlim_{\mathcal{I}} D$ is naturally isomorphic to the functor which maps every object j in \mathcal{J} to the inductive limit of the functor $D(j)$.

Prove the similar result for projective limit.

2.6. Let \mathcal{I} be a **connected category** (that is a nonempty category in which every two objects are connected by a zigzag of morphisms) and X be an object in a category \mathcal{C} . Shows that $X \approx \varprojlim \Delta_X$ and $\varinjlim \Delta_X \approx X$. [Hint: one can direct check them. Or first prove them in **Set**, then use 2.4.]

§2.4 Products and coproducts

Definition 2.4.1. Consider a diagram of shape \mathcal{I} , where \mathcal{I} is a discrete category, it looks like a family of objects without arrows between them. A limit of such a diagram is called a **product** of these objects. Dually, a colimit of such a diagram is called a **coproduct** of these objects.

More explicitly, a product of a family of objects $\{A_i\}_{i \in I}$ is an object P equipped with a family of “projections” $\{p_i: P \rightarrow A_i\}_{i \in I}$ satisfying the following universal property:

For any object T and morphisms $\{t_i: T \rightarrow A_i\}_{i \in I}$, there exist a unique morphism $T \rightarrow P$ making the triangles commutative:

$$\begin{array}{ccc} T & \xrightarrow{\exists!} & P \\ & \searrow t_i & \downarrow p_i \\ & & A_i \end{array}$$

Remark. Since the product (resp. coproduct) is unique up to unique isomorphism, it make sense to write “the” product (resp. coproduct) of a family of objects $\{A_i\}_{i \in I}$ and we often denote it by $\prod_{i \in I} A_i$ (resp. $\coprod_{i \in I} A_i$).

Remark. The product of two objects A and B is traditionally denoted by $A \times B$. A morphism from a cone (C, f, g) to the product $A \times B$ is the unique factorization of f and g through $A \times B$. It is usually denoted by $\langle f, g \rangle$.

Example 2.4.2. Let $f: A \rightarrow B$ be a morphism, then $(A, 1_A, f)$ is also a cone over the diagram of two discrete objects A, B . The unique cone-morphism $\langle 1_A, f \rangle$ is called the **graph** of f and denoted by Γ_f .

Remark. It is a common mistake to think that the projections of a product are epimorphisms. This is not true, not even in the category **Set**.

Another common mistake is to think that once the object $\prod_{i \in I} A_i$ in a product has been fixed, the corresponding projections are necessarily unique. It is not at all.

Since the nullary discrete category is the empty category, the **nullary product** is just the terminal object. Similar, the **unary product** of any object is itself.

Since a binary discrete category is itself symmetric and can be viewed as a full subcategory of a trinary discrete category, the **binary product** is a commutative associative binary operation on a category.

More general, we have

Proposition 2.4.3. *Consider a set I and a partition $I = \bigcup_{k \in K} J_k$ of this set into disjoint subsets. Consider a family $\{C_i\}_{i \in I}$ of objects in a category \mathcal{C} . When all the products involved exist, the following isomorphism holds:*

$$\prod_{i \in I} C_i \approx \prod_{k \in K} \left(\prod_{j \in J_k} C_j \right)$$

Remark. It should be noticed that the existence of the product of a family of objects does not imply the existence of the product of a subfamily of those objects. For example, consider the full subcategory \mathbf{Set}_n of \mathbf{Set} whose objects are the sets with fewer than n elements. It is easy to prove that products in \mathbf{Set}_n , when they exist, are just cartesian products of sets. Therefore the product of two sets with i and j elements exists in \mathbf{Set}_n precisely when $ij < n$. But the product of an arbitrary family containing the empty set always exists: it is just the empty set.

By duality, we have similar facts for **nullary coproduct**, **unary coproduct**, **binary coproduct** and, more general,

Proposition 2.4.4. *Consider a set I and a partition $I = \bigcup_{k \in K} J_k$ of this set into disjoint subsets. Consider a family $\{C_i\}_{i \in I}$ of objects in a category \mathcal{C} . When all the products involved exist, the following isomorphism holds:*

$$\prod_{i \in I} C_i \approx \prod_{k \in K} \left(\prod_{j \in J_k} C_j \right)$$

Example 2.4.5. In \mathbf{Set} , products are just the cartesian products, while coproducts are the disjoint unions.

$$\prod_{i \in I} X_i = \{(x_i, i) \mid x_i \in X_i, i \in I\}$$

Example 2.4.6. In \mathbf{Cat} , products are the products of categories, while coproducts are the category whose objects and hom-sets are disjoint unions.

§2.5 Equalizers and coequalizers

Definition 2.5.1. Let $f, g: A \rightarrow B$ be two parallel morphisms, which can be view as a diagram. an **equalizer** is a limit of the diagram. Dually, a **coequalizer** is a colimit.

Remark. Since the equalizer (resp. coequalizer) is unique up to unique isomorphism, it make sense to write “the” equalizer (resp. coequalizer) of two parallel morphisms $f, g: A \rightarrow B$ and we often denote it by $\ker(f, g)$ (resp. $\operatorname{coker}(f, g)$). The notation follows from the alternative name: the **difference kernel** (resp. **difference cokernel**).

Proposition 2.5.2. *An equalizer (resp. coequalizer) of two morphisms must be monic (resp. epi).*

Proof. Let (K, k) be an equalizer of $f, g: A \rightarrow B$. For any parallel morphisms $u, v: T \rightarrow K$ such that $k \circ u = k \circ v$, the composition $k \circ u$ itself is a cone over $f, g: A \rightarrow B$. Thus it must factor through K by a unique morphism $T \rightarrow K$, which force $u = v$.

Similar argument shows that a coequalizer must be epi. \square

Proposition 2.5.3. *An epi equalizer must be an isomorphism. A monic coequalizer must be an isomorphism.*

Proof. Let (K, k) be an epi equalizer of $f, g: A \rightarrow B$, then $f \circ k = g \circ k$ implies $f = g$. Thus $(A, 1_A)$ is also an equalizer, which force k to be an isomorphism. The proof for monic coequalizer is similar. \square

Example 2.5.4. In **Set**, the equalizer of two functions $f, g: X \rightarrow Y$ is

$$K = \{x \in X \mid f(x) = g(x)\}$$

and the coequalizer is $C = Y/K$, i.e. the quotient set of Y with the equivalence relation generated by $f(x) \sim g(x)$ for all $x \in X$.

Example 2.5.5. Coequalisers can be large: There are exactly two functors from the category **1** having one object and one identity arrow, to the category **2** with two objects and exactly one non-identity arrow going between them. The coequaliser of these two functors is the monoid of natural numbers under

addition, considered as a one-object category. In particular, this shows that while every coequalising arrow is epic, it is not necessarily surjective.

Exercises

2.7. Describe a coproduct of a family of objects $\{A_i\}_{i \in I}$ by a universal property.

2.8. Describe an equalizer and a coequalizer of two parallel morphisms by universal properties.

§2.6 Pullbacks and pushouts

Definition 2.6.1. Let \mathcal{I} be

$$\cdot \longleftarrow \cdot \longrightarrow \cdot$$

then a projective system of shape \mathcal{I} is of the form

$$A \xrightarrow{f} C \xleftarrow{g} B$$

Thus a limit of it can be view as a commutative square:

$$\begin{array}{ccc} P & \xrightarrow{f'} & B \\ g' \downarrow & & \downarrow g \\ A & \xrightarrow{f} & C \end{array}$$

we call it a **pullback square** or **cartesian diagram**, and say g' is the **pullback** of g through f , f' is the **pullback** of f through g . We also call this limit a **fibre product** of A and B over C , and denote it by $A \times_C B$.

A inductive system of shape \mathcal{I} is of the form

$$B \xleftarrow{g} C \xrightarrow{f} A$$

Thus a colimit of it can be view as a commutative square in \mathcal{C} :

$$\begin{array}{ccc} C & \xrightarrow{f} & A \\ g \downarrow & & \downarrow g' \\ B & \xrightarrow{f'} & P \end{array}$$

we call it a **pushout square** or **cocartesian diagram**, and say g' is the **pushout** of g through f , f' is the **pushout** of f through g . We also call this limit the **fibre sum** or **amalgamed sum** of A and B under C , and denoted by $A \amalg_C B$.

Proposition 2.6.2. *Monomorphisms are **stable** under pullback, that means the pullback of a monomorphism is also a monomorphism. Moreover, so are isomorphisms.*

Proof. Assume $g: B \rightarrow C$ is monic and $g': P \rightarrow A$ is its pullback through $f: A \rightarrow C$. Let $u, v: T \rightarrow P$ be two parallel morphisms such that $g' \circ u = g' \circ v$, then

$$g \circ f' \circ u = f \circ g' \circ u = f \circ g' \circ v = g \circ f' \circ v$$

Thus $f' \circ u = f' \circ v$. Therefore T equipped with compositions $g' \circ u, g \circ f' \circ u$ and $f' \circ v$ is a cone over the diagram, which force $u = v$.

Similar, assume g is an isomorphism and g' is its pullback through f . Then A equipped with 1_A and $g^{-1} \circ f$ is a cone over the diagram, which force A itself be a fibre product as P , thus g' is an isomorphism. \square

Remark. Epimorphisms may not be stable under pullback.

By the duality principle, it is easy to get corresponding properties for pushouts from the knowledge of pullbacks.

Kernel pairs

Definition 2.6.3. A **kernel pair** of a morphism in a category is the fiber product of the morphism with itself.

Proposition 2.6.4. Let (P, α, β) be a kernel pair of a morphism $f: A \rightarrow B$, then α, β are split epimorphisms.

Proof. Since $(A, 1_A, 1_A)$ is a cone over the diagram, there exists a unique morphism $t: A \rightarrow P$ such that $1_A = \alpha \circ t = \beta \circ t$. Thus α, β are retractions of t and must be split epimorphisms. \square

Proposition 2.6.5. Consider a morphism $f: A \rightarrow B$, then followings are equivalent:

1. f is a monomorphism;
2. the kernel pair of f exists and is given by $(A, 1_A, 1_A)$;
3. the kernel pair (P, α, β) of f exists and is such that $\alpha = \beta$.

Proposition 2.6.6. In a category, if a coequalizer has a kernel pair, then it is a coequalizer of its kernel pair.

Proof. Consider the following diagram

$$\begin{array}{ccccc}
 & & X & & \\
 & z \swarrow & \downarrow x & \downarrow y & \\
 P & \xrightarrow{\alpha} & A & \xrightarrow{f} & B \\
 & \searrow \beta & \downarrow g & \swarrow h & \\
 & & C & &
 \end{array}$$

where, $f = \text{coker}(x, y)$ and α, β is the kernel pair of f . Hence there exists a unique factorization z such that $\alpha \circ z = x, \beta \circ z = y$. We need to show that $f = \text{coker}(\alpha, \beta)$.

To do this, consider an arbitrary morphism g such that $g \circ \alpha = g \circ \beta$. Then $g \circ x = g \circ \alpha \circ z = g \circ \beta \circ z = g \circ y$. Thus we get a unique factorization h through $f = \text{coker}(x, y)$. \square

Conversely, we have

Proposition 2.6.7. *In a category, if a kernel pair has a coequalizer, then it is a kernel pair of its coequalizer.*

Proof. Consider the following diagram

$$\begin{array}{ccccc}
 & & X & & \\
 & z \swarrow & \downarrow x & \downarrow y & \\
 P & \xrightarrow{\alpha} & A & \xrightarrow{f} & B \\
 & \searrow \beta & \downarrow g & \swarrow h & \\
 & & C & &
 \end{array}$$

where, α, β is the kernel pair of g and $f = \text{coker}(\alpha, \beta)$. Since $g \circ \alpha = g \circ \beta$, we get a unique factorization h through $f = \text{coker}(\alpha, \beta)$. We need to show that α, β is the kernel pair of f .

To do this, consider two parallel morphisms x, y such that $f \circ x = f \circ y$. Then $g \circ x = h \circ f \circ x = h \circ f \circ y = g \circ y$. Thus there exists a unique factorization z such that $\alpha \circ z = x, \beta \circ z = y$. \square

Diagram chase

When deal with universal properties, people often check equations along the commutative diagram, such a method is called **diagram chase**.

The following proportion is a good example.

Proposition 2.6.8 (Associativity). *Consider a commutative diagram as below:*

1. *If the two small squares are cartesian, then so is the outer rectangle.*
2. *If the right square and the outer rectangle are cartesian, then so is the left square.*

Proof. For 1, since we want to prove the outer rectangle is cartesian, we draw a commutative diagram as below:

More explicitly, let u, v be two morphisms from a same domain and is such that $g \circ f \circ u = e \circ v$. Then we need to show that there exists a unique morphism w such that $c \circ w = u, b \circ a \circ w = v$.

To prove the existence, we chase the diagram as following:

1, Since $g \circ f \circ u = e \circ v$ and the right square is cartesian, there exists a unique morphism x such that $d \circ x = f \circ u, b \circ x = v$.

2, Since $d \circ x = f \circ u$ and the left square is cartesian, there exists a unique morphism w such that $c \circ w = u, a \circ w = x$.

3, Since $c \circ w = u, a \circ w = x, b \circ x = v$, we have $c \circ w = u, b \circ a \circ w = v$.

To prove the uniqueness, we assume that there exists a morphism w' such that $c \circ w' = u, b \circ a \circ w' = v$ and prove that $a \circ w' = x$. Then the uniqueness follows from the condition that the left square is cartesian. To do this, we chase the diagram as following:

1, Since $d \circ a = f \circ c$ and $c \circ w' = u$, we have $d \circ a \circ w' = f \circ u$.

2, Since $d \circ a \circ w' = f \circ u, b \circ a \circ w' = v$ and the right square is cartesian, $a \circ w' = x$.

For 2, since we want to prove the left square is cartesian, we draw a commutative diagram as below:

More explicitly, let u, v be two morphisms from a same domain and is such that $f \circ u = d \circ v$. Then we need to show that there exists a unique morphism w such that $c \circ w = u, a \circ w = v$.

To prove the existence, we chase the diagram as following:

- 1, Since $e \circ b = g \circ d$ and $f \circ u = d \circ v$, we have $g \circ f \circ u = e \circ b \circ v$.
- 2, Since $g \circ f \circ u = e \circ b \circ v$ and the outer rectangle is cartesian, there exists a unique morphism w such that $c \circ w = u, b \circ a \circ w = b \circ v$.
- 3, Since $d \circ a = f \circ c$ and $c \circ w = u$, we have $d \circ a \circ w = f \circ u$.
- 4, Since $d \circ a \circ w = f \circ u, b \circ a \circ w = b \circ v$ and the right square is cartesian, $a \circ w = v$.

To prove the uniqueness, we assume that there exists a morphism w' such that $c \circ w' = u, a \circ w' = v$ and prove that $b \circ a \circ w' = b \circ v$. Then the uniqueness follows from the condition that the outer rectangle is cartesian. However, this is obvious. \square

Corollary 2.6.9. *The pullback of a commutative triangle (if it exists) is a commutative triangle.*

Examples

Example 2.6.10. In the category **Set**, the pullback of pair $A \xrightarrow{f} C \xleftarrow{g} B$ is given by

$$P = \{(a, b) \mid a \in A, b \in B, f(a) = g(b)\},$$

$$g'(a, b) = a, f'(a, b) = b$$

Example 2.6.11. Under the conditions of 2.6.10, when B is a subset of C and g is the canonical inclusion, then P is isomorphic to the fibre $f^{-1}(B)$, i.e. the inverse image of B along f .

Remark. In general, when g is monic, we can write P as $f^{-1}(B)$ and call it “the inverse image of g along f ”.

Example 2.6.12. Under the conditions of 2.6.10, if both A and B are subsets of C with f, g the canonical inclusions, then P is isomorphic to the intersection $A \cap B$.

Remark. In general, when f, g are monic, we can write P as $A \cap B$ and call it “the intersection of f and g ”.

Example 2.6.13. In the category **Set**, the kernel pair of a function f is just the equivalence relation on A determined by f .

Exercises

2.9. Describe pullbacks and pushouts by universal properties.

2.10. Describe the corresponding concepts and propositions in this section for pushouts. Then prove these propositions.

2.11. Let $A \xrightarrow{f} C \xleftarrow{g} B$ be a pair of morphisms, and $(A \times B, p_A, p_B)$ be a product of A and B , $e: E \rightarrow A \times B$ is an equalizer of $f \circ p_A$ and $g \circ p_B$. Then the following diagram is cartesian:

$$\begin{array}{ccc} E & \xrightarrow{p_B \circ e} & B \\ p_A \circ e \downarrow & & \downarrow g \\ A & \xrightarrow{f} & C \end{array}$$

Conversely, if there exists a morphism $e: E \rightarrow A \times B$ making the above square cartesian, then (E, e) is an equalizer of $f \circ p_A$ and $g \circ p_B$.

§2.7 Limits and colimits in Set

Proposition 2.7.1. *The initial object in **Set** is the empty set \emptyset , while a terminal object is a singleton **Pt**.*

Proposition 2.7.2. *The product of a set of sets $\{X_i\}_{i \in I}$ is the usual cartesian product of them: $\prod_{i \in I} X_i = \{(x_i)_{i \in I} \mid \forall i \in I, x_i \in X_i\}$. The coproduct of them is the disjoint union $\bigsqcup_{i \in I} X_i = \{(i, x) \mid i \in I, x \in X_i\}$.*

Proposition 2.7.3. *the product of all sets is the empty set \emptyset . Indeed, any product of a set of sets which involves \emptyset must be \emptyset itself. However, the coproduct of all sets do not exists.*

Proposition 2.7.4. *The equalizer of two parallel functions $f_0, f_1: S \rightarrow T$ is the subset of S : $\{s \in S \mid f_0(s) = f_1(s)\}$. The coequalizer of them is the quotient set of T by the equivalence relation $R \subset T \times T$ generated by $\{(f_0(s), f_1(s)) \mid s \in S\}$. More explicitly, for any $x, y \in T$, XRy means there exists a sequence of elements $s_1, \dots, s_n \in S$ and a sequence of binary digits $\epsilon_1, \dots, \epsilon_n$ such that*

$$\begin{aligned} f_{\epsilon_1}(s_1) &= x \\ &\dots \\ f_{1-\epsilon_i}(s_i) &= f_{\epsilon_{i+1}}(s_{i+1}) \\ &\dots \\ f_{1-\epsilon_n}(s_n) &= y \end{aligned}$$

Proposition 2.7.5. *The fibre product of $f: A \rightarrow C$ and $g: B \rightarrow C$ is the subset of the cartesian product: $A \times_C B = \{(a, b) \mid f(a) = g(b)\} \subset A \times B$.*

Proposition 2.7.6. *The amalgamed sum of $f: C \rightarrow A$ and $g: C \rightarrow B$ is the quotient of the disjoint union: $A \amalg_C B = (A \sqcup B)/R$ by the equivalence relation R generated by $\{(f(s), g(s)) \mid s \in C\}$*

Proposition 2.7.7. *The limit of $D: \mathcal{I}^{\text{op}} \rightarrow \mathbf{Set}$ is the set of natural transformations from the diagram constant on the singleton to D , or equivalently, the set of global elements of D .*

To give an explicit description, let $D: \mathcal{I}^{\text{op}} \rightarrow \mathbf{Set}$ be a small diagram, it is not difficult to see that a cone over the diagram D is the same thing as a cone over the following diagram: (For brevity, we abbreviate “target of f ” and “source of f ” just as $t.f$, $s.f$.)

$$\prod_{i \in \text{ob } \mathcal{I}} D_i \underset{\beta}{\overset{\alpha}{\rightrightarrows}} \prod_{f \in \text{hom } \mathcal{I}} D_{s.f}$$

Where α, β is given by

$$\begin{aligned} \alpha(x_i)_{i \in \text{ob } \mathcal{I}} &= (x_{s.f})_{f \in \text{hom } \mathcal{I}} \\ \beta(x_i)_{i \in \text{ob } \mathcal{I}} &= (D_f(x_{t.f}))_{f \in \text{hom } \mathcal{I}} \end{aligned}$$

Therefore, the limit L of D can be given by the equalizer

$$L \rightrightarrows \prod_{i \in \text{ob } \mathcal{I}} D_i \underset{\beta}{\overset{\alpha}{\rightrightarrows}} \prod_{f \in \text{hom } \mathcal{I}} D_{s.f}$$

More explicitly,

$$L = \{(x_i)_{i \in \text{ob } \mathcal{I}} \mid x_i \in D_i; D_f(x_i) = x_j, \forall f: j \rightarrow i\}$$

Dually, let $D: \mathcal{I} \rightarrow \mathbf{Set}$ be a small diagram, the colimit C of D can be given by the coequalizer

$$\bigsqcup_{f \in \text{hom } \mathcal{I}} D_{s.f} \underset{\beta}{\overset{\alpha}{\rightrightarrows}} \bigsqcup_{i \in \text{ob } \mathcal{I}} D_i \twoheadrightarrow C$$

Where α, β is given by

$$\begin{aligned} \alpha(x_{s.f} \in D_{s.f}) &= x_{s.f} \in D_{s.f} \\ \beta(x_{s.f} \in D_{s.f}) &= D_f(x_{s.f}) \in D_{t.f} \end{aligned}$$

The colimit of D is given by a quotient set

$$\varinjlim D = (\bigsqcup_{i \in \text{ob } \mathcal{I}} D_i) / \sim$$

where the equivalence relation \sim is that which is generated by

$$\{(x \in D_i) \sim (x' \in D_{i'}) \mid \exists (f: i \rightarrow i') \text{ s.t. } (D_f(x) = x')\}$$

§2.8 Complete categories

In a category \mathcal{C} , if every diagram of shape \mathcal{I} admits a limit (resp. colimit), then we say it **has** all \mathcal{I} -limits (resp. \mathcal{I} -colimits). For instance, the category **Set** has all pullbacks, pushouts, kernel pairs, cokernel pairs, equalizers, coequalizers and has products and coproducts of a set of objects. In later body, one can see the existence of previous limits (resp. colimits) ensure **Set** has all small limits (resp. colimits).

Such a category is undoubtedly very nice, thus one may ask when a category has all limits or colimits.

Definition 2.8.1. A category is said to be **complete**, if every small diagram in it has a limit. Similar, a **finitely complete category** is such a category, in which every finite diagram has a limit. Dually, we have concepts of **cocomplete category** and **finitely cocomplete category**.

Large (not small) limits may exists. For example, the product of all sets in **Set** is the empty set.

However, this is an exception. Indeed, a category has all limits must be **thin**. That is, its every hom-set is a singleton.

We do not prove this. Instead, we give a similar proposition.

Proposition 2.8.2. *A complete small category must be thin.*

Proof. Let \mathcal{C} be a complete small category. For any pair of objects A, B in \mathcal{C} and any $f, g \in \text{Hom}(A, B)$. We need to show $f = g$.

If not, then consider the product of κ copies of B , say B^κ . Where κ is the cardinal of the set of all arrows of \mathcal{C} . Then, use f and g , one can already construct 2^κ distinct cones over the copies of B , each of them admits a factorization $A \rightarrow B^\kappa$. From this, it is clear that $\text{Hom}(A, B^\kappa)$ has the cardinal no less than 2^κ , which contracts with the assumption of κ . \square

Based on the same reasoning, a category has all limits with index category larger than itself must be thin. Particularly, a finite complete finite category must be a finite preordered set.

Our next goal is to get the condition of completeness for non-small categories.

Consider our most familiar category **Set**. Let $D: \mathcal{I}^{\text{op}} \rightarrow \mathbf{Set}$ be a small diagram, it is not difficult to see that a cone over the diagram D is the same thing as a cone over the following diagram: (For brevity, we abbreviate “target of f ” and “source of f ” just as $t.f$, $s.f$.)

$$\prod_{i \in \text{ob } \mathcal{I}} D_i \begin{array}{c} \xrightarrow{\alpha} \\ \xrightarrow{\beta} \end{array} \prod_{f \in \text{hom } \mathcal{I}} D_{s.f}$$

Where α, β is given by

$$\begin{aligned} \alpha(x_i)_{i \in \text{ob } \mathcal{I}} &= (x_{s.f})_{f \in \text{hom } \mathcal{I}} \\ \beta(x_i)_{i \in \text{ob } \mathcal{I}} &= (D_f(x_{t.f}))_{f \in \text{hom } \mathcal{I}} \end{aligned}$$

Therefore, the limit L of D can be given by the equalizer

$$L \rightrightarrows \prod_{i \in \text{ob } \mathcal{I}} D_i \begin{array}{c} \xrightarrow{\alpha} \\ \xrightarrow{\beta} \end{array} \prod_{f \in \text{hom } \mathcal{I}} D_{s.f}$$

More explicitly,

$$L = \{(x_i)_{i \in \text{ob } \mathcal{I}} \mid x_i \in D_i; D_f(x_i) = x_j, \forall f: j \rightarrow i\}$$

This construction can be generalized to an arbitrary category. Thus we get the following theorem.

Theorem 2.8.3. *A category \mathcal{C} is complete if and only if each set of objects has a product and each pair of parallel arrows has an equalizer.*

Proof. It suffices to show the “if”.

Let $D: \mathcal{I}^{\text{op}} \rightarrow \mathcal{C}$ be a small diagram. We construct the products

$$\prod_{i \in \text{ob } \mathcal{I}} D_i \quad \& \quad \prod_{f \in \text{hom } \mathcal{I}} D_{s.f}$$

with $\{p'_i\}_{i \in \text{ob } \mathcal{I}}$ and $\{p''_f\}_{f \in \text{hom } \mathcal{I}}$ be their respective projections.

Let α be the unique factorization such that $p''_f \circ \alpha = p'_{s.f}$, β be the unique factorization such that $p''_f \circ \beta = D_f \circ p'_{t.f}$, and (L, l) be the equalizer of pair (α, β) . Denote each $p'_i \circ l$ by p_i , now we prove that $(L, (p_i)_{i \in \text{ob } \mathcal{I}})$ is

a limit of D .

$$\begin{array}{ccccc}
& & q' & & \\
& \swarrow & \text{---} & \searrow & \\
C & \xrightarrow[\bar{q}]{q} L & \xrightarrow{l} \prod_{i \in \text{ob } \mathcal{I}} D_i & \xrightarrow[\beta]{\alpha} \prod_{f \in \text{hom } \mathcal{I}} D_{s.f} \\
& \searrow p_i & \downarrow p'_i & \searrow p'_j & \downarrow p''_f \\
& & D_i & \xrightarrow{D_f} D_j & \\
& \searrow q_i & & &
\end{array}$$

First, it is a cone over D . Indeed, for any arrow $f: j \rightarrow i$, we have

$$\begin{aligned}
D_f \circ p_i &= D_f \circ p'_i \circ l \\
&= p''_f \circ \beta \circ l \\
&= p''_f \circ \alpha \circ l \\
&= p'_j \circ l = p_j
\end{aligned}$$

Moreover, let $(C, (q_i)_{i \in \text{ob } \mathcal{I}})$ be another cone over D , we need to show that there exists a unique **Cone**(D)-morphism q , that is a unique factorization q such that $p_i \circ q = q_i$.

Since $(C, (q_i)_{i \in \text{ob } \mathcal{I}})$ is also a cone over the family of objects $\{D_i\}_{i \in \text{ob } \mathcal{I}}$. There exists a unique factorization q' such that $p'_i \circ q' = q_i$.

For each arrow $f: j \rightarrow i$, we have

$$\begin{aligned}
p''_f \circ \alpha \circ q' &= p'_j \circ q' \\
&= q_j \\
&= D_f \circ q_i \\
&= D_f \circ p'_i \circ q' \\
&= p''_f \circ \beta \circ q'
\end{aligned}$$

From which $\alpha \circ q' = \beta \circ q'$. This implies the existence of the factorization q such that $l \circ q = q'$. Then

$$p_i \circ q = p'_i \circ l \circ q = p'_i \circ q' = q_i$$

So this q is our require factorization.

The uniqueness is easy to see by the universal property of equalizer. Or, consider another factorization \bar{q} such that $p_i \circ \bar{q} = q_i$. Since l must be

monic, it suffices to show $l \circ q = l \circ \bar{q}$. Indeed, for any $i \in \text{ob } \mathcal{I}$, we have

$$\begin{aligned} p'_i \circ l \circ q &= p'_i \circ q' \\ &= q_i \\ &= p_i \circ \bar{q} \\ &= p'_i \circ l \circ \bar{q} \end{aligned}$$

Then, by Proposition 2.3.7, $l \circ q = l \circ \bar{q}$. □

Proposition 2.8.4. *For a category \mathcal{C} , the followings are equivalent.*

1. \mathcal{C} is finitely complete;
2. \mathcal{C} has terminal objects, binary products and equalizers;
3. \mathcal{C} has terminal objects and pullbacks.

Proof. $1 \Rightarrow 2$ and $1 \Rightarrow 3$ are obvious. $2 \Rightarrow 3$ comes from Exercise 2.11. Or, by the associativity of products (see 2.4.3) and induction, 2 implies the existence of products of finite and non-empty family of objects. Notice that, in the proof of Theorem 2.8.3, when the diagram D is finite, then so are the corresponding products, therefore $2 \Rightarrow 1$.

To show $3 \Rightarrow 2$, we assume 3. It is obvious that a fibre product over the terminal object is just a product. To show the existence of equalizers, consider a pair of morphisms $f, g: A \rightrightarrows B$. For any triple (P, k, l) making the following square commutative

$$\begin{array}{ccc} P & \xrightarrow{l} & A \\ k \downarrow & & \downarrow \Gamma_g \\ A & \xrightarrow{\Gamma_f} & A \times B \end{array}$$

we have

$$\begin{aligned} k &= p_A \circ \Gamma_f \circ k = p_A \circ \Gamma_g \circ l = l \\ f \circ k &= p_B \circ \Gamma_f \circ k = p_B \circ \Gamma_g \circ l = g \circ l \end{aligned}$$

This implies that $k = l$ and (P, k) is a cone over the pair (Γ_f, Γ_g) . Therefore the pullback of (Γ_f, Γ_g) is precisely the equalizer of (f, g) . □

Definition 2.8.5. A category \mathcal{I} is said to be finitely generated if

- \mathcal{I} has finitely many objects;
- there are finitely many arrows f_1, \dots, f_n such that each arrow of \mathcal{I} is the composite of finitely many of these f_i .

Proposition 2.8.6. Let D be a diagram in a finitely complete category. If the index category of D is finitely generated, then $\varprojlim D$ exists.

Proof. Notice that a cone over D is uniquely determined by these D_{f_i} , thus we can replace the second product in the proof of 2.8.3 by $\prod_{i=1}^n D_{s.f_i}$, and the statement follows. \square

Exercises

2.12. Describe and verify the dual notations and propositions in this section for colimit.

2.13. Let \mathcal{C} be a complete category and \mathcal{I} a small category. Then taking projective limit objects is a functor from $[\mathcal{I}^{\text{op}}, \mathcal{C}]$ to \mathcal{C} , while taking inductive limit objects is a functor from $[\mathcal{I}, \mathcal{C}]$ to \mathcal{C} .

2.14. Product preserving monomorphisms. That is the product of a family of monomorphisms is also a monomorphism.

2.15. Let \mathcal{C} be a complete category and $f: A \rightarrow B$ a morphism in \mathcal{C} . Then taking pullback along f is a functor from \mathcal{C}/B to \mathcal{C}/A and taking pushout is a functor from A/\mathcal{C} to B/\mathcal{C} .

§2.9 Persevering limits

In this section and the followings, we will consider how limits or colimits behave under functors. Thus to view them as natural transformations may be more suitable.

Definition 2.9.1. A functor $F: \mathcal{A} \rightarrow \mathcal{B}$ is said to **preserve limits** of shape \mathcal{I}^{op} if, whenever $\mu: \Delta_L \Rightarrow D$ is a limit of a diagram $D: \mathcal{I}^{\text{op}} \rightarrow \mathcal{A}$, the cone $F * \mu$ is then a limit of the diagram $F \circ D: \mathcal{I}^{\text{op}} \rightarrow \mathcal{B}$. Briefly

$$F(\varprojlim D) \approx \varprojlim F \circ D$$

A functor that preserves all small limits is simply said to **preserve limits** and is called a **continuous functor**.

Remark. From the definition, one can see that a functor preserving limits of shape \mathcal{I}^{op} also preserving the existence of limits of \mathcal{I}^{op} -diagrams. Indeed, $F(\varprojlim D)$ gives a limit of $F \circ D$.

As an immediate consequence of Theorem 2.8.3, we get

Proposition 2.9.2. *Let \mathcal{A} be a (finitely) complete category and \mathcal{B} an arbitrary category. A functor $F: \mathcal{A} \rightarrow \mathcal{B}$ preserves (finite) limits precisely when it preserves (finite) products and equalizers.*

By Proposition 2.6.5, we have

Proposition 2.9.3. *A functor which preserves pullbacks also preserves monomorphisms.*

The following proposition provides examples of continuous functors.

Proposition 2.9.4. *A covariant representable functor is continuous. Moreover, it preserves all existing limits including large ones.*

Proof. It suffices to show that for any $C \in \text{ob } \mathcal{C}$ and D a diagram in \mathcal{C} , we have

$$\text{Hom}(C, \varprojlim D) \approx \varprojlim \text{Hom}(C, D)$$

Which is precisely Proposition 2.3.9. □

Similarly, we have

Proposition 2.9.5. *A representable presheaf transforms colimits into limits and epimorphisms to monomorphisms.*

A related concept of preserving limits is reflecting limits.

Definition 2.9.6. A functor $F: \mathcal{A} \rightarrow \mathcal{B}$ is said to **reflect limits** of shape \mathcal{I}^{op} when, for each cone $\mu: \Delta_L \Rightarrow D$ over a diagram $D: \mathcal{I}^{\text{op}} \rightarrow \mathcal{A}$, it is a limit of D if its image $F * \mu$ is a limit of the diagram $F \circ D: \mathcal{I}^{\text{op}} \rightarrow \mathcal{B}$. A functor that reflects all small limits is simply said to **reflect limits**.

Remark. A limits reflecting functor may **not** ensure the existence of limits. It is possible that the diagram $F \circ D$ has limits in \mathcal{B} but none of them has a preimage in \mathcal{A} .

Proposition 2.9.7. *Let $F: \mathcal{A} \rightarrow \mathcal{B}$ be a continuous functor. If \mathcal{A} is complete and F reflects isomorphisms, then F also reflects limits.*

Proof. Let $\mu: \Delta_C \Rightarrow D$ be a cone over a small diagram $D: \mathcal{I}^{\text{op}} \rightarrow \mathcal{A}$ such that $F * \mu$ is a limit of $F \circ D$.

Since \mathcal{A} is complete, there exists a limit $\nu: \Delta_L \Rightarrow D$ of D and a unique factorization $f: C \rightarrow L$ of μ by ν .

The continuous functor F transforms it to a limit $F * \nu$ of $F \circ D$ and f to an isomorphism between these two limits of $F \circ D$.

Since F reflects isomorphisms, f is also an isomorphism and thus μ is a limit of D . \square

Proposition 2.9.8. *Let \mathcal{A}, \mathcal{B} be finitely complete categories and $F: \mathcal{A} \rightarrow \mathcal{B}$ a functor which preserves (resp. reflects) finite limits. Then F preserves (resp. reflects) finitely generated limits.*

Proof. A finitely generated limit can be expressed via equalizers and finite products (see 2.8.6), from which the result follows. \square

Proposition 2.9.9. *A fully faithful functor reflects limits.*

Proof. Notice that a fully faithful functor reflects terminal objects, thus the result follows. \square

Exercises

2.16. Describe the corresponding concepts (“preserve colimits”, “cocontinuous functor”, “reflect colimit”) and propositions for colimits and then prove them.

2.17. Consider a category \mathcal{C} having products and a diagram D with small index category. Construct α and β as in the proof of Theorem 2.8.3. Prove that $\ker(\alpha, \beta)$ exists if and only if $\varprojlim D$ exists.

2.18. Consider a category \mathcal{A} having products and a functor $F: \mathcal{A} \rightarrow \mathcal{B}$ preserving products and equalizers. Show that F preserves limits.

§2.10 Absolute colimits

In the previous section we were concerned with a functor preserving all limits. Now we shall have a look at those limits preserved by all functors. In fact we shall develop the theory in the case of colimits since this is the case most commonly referred to in the examples.

Definition 2.10.1. A particular colimit diagram in a category \mathcal{C} is called an **absolute colimit** if it is preserved by every functor with domain \mathcal{C} .

In general a colimit is absolute because the colimit is a colimit for purely “diagrammatic” reasons. For instance, split epimorphisms is absolute in this sense, because of the equation describe the section of a split epimorphism is preserved under any functor. While, an general epimorphism may be not absolute.

Example 2.10.2. Initial objects are never absolute. Indeed, if 0 is an initial object, then it is never preserved by the covariant representable functor $\text{hom}(0, -): \mathcal{C} \rightarrow \mathbf{Set}$.

Example 2.10.3. Similarly, coproducts are never absolute.

Example 2.10.4. The trivial example for absolute coequalizers is that the coequalizer of a pair of same epimorphism is absolute. Indeed, it is just the identity of codomain.

The most common example is a split coequalizer.

Definition 2.10.5. A **split coequalizer** (C, e) of a pair (f, g) is a co-cone under this pair such that the morphism $(f, e): g \rightarrow e$ has a section in the arrow category.

Proposition 2.10.6. *A split coequalizer is an absolute coequalizer.*

Proof. Let $(r, s): e \rightarrow g$ be a section of (f, e) in the arrow category. Then we have

$$f \circ r = 1_B \quad e \circ s = 1_C \quad s \circ e = g \circ r$$

By the definition, (C, e) is a co-cone under the pair (f, g) . Now we consider another co-cone (D, p) . Define $q = p \circ s$, then we have

$$\begin{aligned}
 q \circ e &= p \circ s \circ e \\
 &= p \circ g \circ r \\
 &= p \circ f \circ r \\
 &= p
 \end{aligned}$$

and if there exists another \bar{q} such that $\bar{q} \circ e = p$, then

$$\begin{aligned}
 \bar{q} &= \bar{q} \circ e \circ s \\
 &= p \circ s \\
 &= q
 \end{aligned}$$

So, (C, e) is a coequalizer of (f, g) . Moreover, since the equalities of the statement are preserved by any functor, the same conclusion applies to the image of above diagram under any functor. \square

We now give a general characterization of absolute coequalizers, the previous example are just special cases of it.

Proposition 2.10.7. *Let (C, e) be a co-cone under a pair $f_0, f_1: A \rightarrow B$. (C, e) is an absolute coequalizer of (f_0, f_1) if and only if there exist a section s of e , a sequence of morphisms $r_1, \dots, r_n: B \rightarrow A$ and a sequence of binary digits $\epsilon_1, \dots, \epsilon_n$ such that*

$$\begin{aligned}
 e \circ s &= 1_C \\
 f_{\epsilon_1} \circ r_1 &= 1_B \\
 &\dots \\
 f_{1-\epsilon_i} \circ r_i &= f_{\epsilon_{i+1}} \circ r_{i+1} \\
 &\dots \\
 f_{1-\epsilon_n} \circ r_n &= s \circ e
 \end{aligned}$$

Proof. To show the “only if”, just notice that, an absolute coequalizer must be preserved, in particular, by the hom-functor $\text{Hom}(C, -)$ and $\text{Hom}(B, -)$.

The previous one shows the function $e_*: \text{Hom}(C, B) \rightarrow \text{Hom}(C, C)$ is split epi, thus the existence of the section s follows. The latter one shows that 1_B and $s \circ e$ are in the same equivalence class in $\text{Hom}(B, B)$ under the equivalence relation generated by the image of $(f_0, f_1): A \rightarrow B \times B$, thus there exists a sequence connected them.

Conversely, it is easy to check that if such section s and sequence r_1, \dots, r_n exist, the given co-cone must be a coequalizer, for essentially the same reasoning in the proof of Proposition 2.10.6. \square

More generally, we offer some pleasant characterizations for absolute colimits.

Theorem 2.10.8. *For a co-cone $\mu: D \Rightarrow \Delta_C$ under a diagram $D: \mathcal{I} \rightarrow \mathcal{C}$, the followings are equivalent:*

1. μ is an absolute colimit.
2. μ is a colimit which is preserved by the Yoneda embedding Υ .
3. μ is a colimit which is preserved by the covariant representable functors $\text{Hom}(D_i, -): \mathcal{C} \rightarrow \mathbf{Set}$ (for all $i \in \text{ob } \mathcal{I}$) and $\text{Hom}(C, -): \mathcal{C} \rightarrow \mathbf{Set}$.
4. There exists $i_0 \in \text{ob } \mathcal{I}$ and $d_0: C \rightarrow D_{i_0}$ such that
 - (a) For every $i \in \text{ob } \mathcal{I}$, $d_0 \circ \mu_i$ and 1_{D_i} are in the same connected component of the comma category $(D_i \downarrow D)$.
 - (b) $\mu_{i_0} \circ d_0 = 1_C$.

Proof. $1 \Rightarrow 2 \Rightarrow 3$ are obvious.

To see $3 \Rightarrow 4$, notice that in \mathbf{Set} , a colimit is a quotient set of the disjoint union of objects in the diagram. Apply this fact to the colimit $\text{Hom}(C, -) * \mu$, we see that $1_C \in \text{Hom}(C, C)$ must have a preimage in some $\text{Hom}(C, D_{i_0})$. That means μ_{i_0} have sections $d_0: C \rightarrow D_{i_0}$. Which is b).

Next we check *a*) for such i_0 and d_0 . To do this, we consider the colimit $\text{Hom}(D_i, -) * \mu$. We have

$$\begin{aligned}\mu_{i_0} \circ d_0 \circ \mu_i &= \mu_i \\ 1_{D_i} \circ \mu_i &= \mu_i\end{aligned}$$

Thus $d_0 \circ \mu_i$ and 1_{D_i} have the same image in the colimit $\text{Hom}(D_i, C)$, which is a quotient set of the disjoint union $\bigsqcup_{j \in \text{ob } \mathcal{I}} \text{Hom}(D_i, D_j)$. Notice that the quotient is under the equivalence relation generated by the morphisms in the diagram D . Then the similar reasoning as in the proof of Proposition 2.10 shows that there exists a sequence of morphisms in the diagram D such that $d_0 \circ \mu_i$ and 1_{D_i} are connected by them. Which is *a*).

Finally, we prove $4 \Rightarrow 1$. Let $\mu: D \Rightarrow \Delta_C$ be a co-cone satisfies the conditions in 4 and $\nu: D \Rightarrow \Delta_T$ be another co-cone. We need to show that there exists a unique factorization $f: C \rightarrow T$ of ν by μ and make sure such a proof is purely “diagrammatic”.

Let $f = \nu_{i_0} \circ d_0$. Then $f \circ \mu_i = \nu_{i_0} \circ (d_0 \circ \mu_i)$. Since $d_0 \circ \mu_i$ and 1_{D_i} are connected in $(D_i \downarrow D)$, we have

$$\begin{aligned}f \circ \mu_i &= \nu_{i_0} \circ (d_0 \circ \mu_i) \\ &\dots \\ &= \nu_i \circ 1_{D_i} = \nu_i\end{aligned}$$

Which shows that f is the required factorization.

To show the uniqueness, consider another factorization \bar{f} . Then

$$\begin{aligned}\bar{f} &= \bar{f} \circ \mu_{i_0} \circ d_0 \\ &= \nu_{i_0} \circ d_0 = f\end{aligned}$$

Therefore, μ is a colimit of D . Moreover, the equations in this proof are obvious preserved by any functor. Thus μ is absolute. \square

Exercises

Example 2.10.9. Let (C, e) be the coequalizer of its kernel pair (f, g) . Shows that if e is split epi, then the coequalizer is split and thus absolute.

§2.11 Final functor

A final functor $F: \mathcal{I} \rightarrow \mathcal{J}$ is which that if we can restrict diagrams on \mathcal{J} to diagrams on \mathcal{I} along F without changing their colimit.

Definition 2.11.1. A functor $F: \mathcal{I} \rightarrow \mathcal{J}$ is said to be **cofinal** if for every object $j \in \mathcal{J}$ the comma category $(j \downarrow F)$ is connected. A functor is said to be **initial** (or **co-cofinal**) if its opposite is final.

Remark. Beware that these properties are pretty much unrelated to that of a functor being an initial object or terminal object in the functor category $[\mathcal{I}, \mathcal{J}]$.

Remark. The prefix “co-” in the term “cofinal” does not mean it is the dual of “final”. Indeed, “**final functor**” is just another name of “cofinal functor”.

Lemma 2.11.2. *Let $F: \mathcal{I} \rightarrow \mathcal{J}$ be a functor and $D: \mathcal{J} \rightarrow \mathcal{C}$ be a diagram. Then any co-cone α under D can be restricted to be a co-cone $\alpha * F$ under $D \circ F$. If F is cofinal, then any co-cone α under $D \circ F$ can be uniquely extended to a co-cone β under D such that $\beta * F = \alpha$.*

Proof. The first statement is obvious, we now prove the second.

For any $j \in \text{ob } \mathcal{J}$, since $(j \downarrow F)$ is nonempty, then there exists an \mathcal{J} -arrow $j \rightarrow F(i)$ for some $i \in \mathcal{I}$. Let β_j be the composite $\alpha_i \circ D(j \rightarrow F(i))$. Then such a morphism β_j is independent for the choice of i . Indeed, for any \mathcal{I} -arrow $i \rightarrow i'$ inducing a morphism in $(j \downarrow F)$, it is easy to see that $\alpha_i \circ D(j \rightarrow F(i)) = \alpha_{i'} \circ D(j \rightarrow F(i'))$. Since $(j \downarrow F)$ is connected, the same thing hold for all objects in it and the result composite is then independent for choice of i . By similar reasoning, it is easy to see that β form a co-cone under D .

Since $\beta_{F(i)} = \alpha_i \circ D(1_{F(i)}) = \alpha_i$, we get $\beta * F = \alpha$.

If there exists another co-cone γ under D such that $\gamma * F = \alpha$, then we have $\gamma_{F(i)} = \alpha_i$ for all $i \in \text{ob } \mathcal{I}$. For any $j \in \text{ob } \mathcal{J}$, since $(j \downarrow F)$ is nonempty, then there exists an \mathcal{J} -arrow $j \rightarrow F(i)$ for some $i \in \mathcal{I}$. Then we have $\gamma_j = \gamma_{F(i)} \circ D(j \rightarrow F(i)) = \alpha_i \circ D(j \rightarrow F(i)) = \beta_j$. \square

Remark. Similar result holds for cones.

Theorem 2.11.3. *Let $F: \mathcal{I} \rightarrow \mathcal{J}$ be a functor, then the following conditions are equivalent.*

1. *F is cofinal.*

2. *For all diagrams $D: \mathcal{J} \rightarrow \mathbf{Set}$ the natural function between colimits*

$$\varinjlim D \circ F \rightarrow \varinjlim D$$

is bijective.

3. *For all categories \mathcal{C} and all diagrams $D: \mathcal{J} \rightarrow \mathcal{C}$ the natural morphism between colimits*

$$\varinjlim D \circ F \rightarrow \varinjlim D$$

is an isomorphism.

4. *For all diagrams $D: \mathcal{J}^{\text{op}} \rightarrow \mathbf{Set}$ the natural function between limits*

$$\varprojlim D \rightarrow \varprojlim D \circ F^{\text{op}}$$

is bijective.

5. *For all categories \mathcal{C} and all diagrams $D: \mathcal{J}^{\text{op}} \rightarrow \mathcal{C}$ the natural morphism*

$$\varprojlim D \rightarrow \varprojlim D \circ F^{\text{op}}$$

is an isomorphism.

6. *For all $j \in \mathcal{J}$*

$$\varinjlim_{i \in \text{ob } \mathcal{I}} \text{Hom}_{\mathcal{J}}(j, F(i)) \approx \text{Pt}$$

where Pt denote a singleton.

Remark. The isomorphisms in these condition should be understood as follows: whenever one of the both sides exists, then so does the other side and the morphism thus exists and must be an isomorphism. Or see 2.4.

Proof. $3 \Rightarrow 2$, $5 \Rightarrow 4$, $2 \Leftrightarrow 4$ and $3 \Leftrightarrow 5$ are obvious.

$1 \Rightarrow 3$. Assume $\varinjlim D \circ F = \nu: D \circ F \Rightarrow \Delta_C$, by Lemma 2.11.2, we can uniquely extended it to a co-cone $\mu: D \Rightarrow \Delta_C$. We now show that it is a colimit of D .

For any co-cone $\tau: D \Rightarrow \Delta_T$ under D , $\tau * F$ is a co-cone under $D \circ F$, then we get a unique factorization $\phi: C \rightarrow T$ of $\tau * F$ by $\nu = \mu * F$. That is $\phi \circ \mu * F = \tau * F$. By Lemma 2.11.2, it can be uniquely extended to a co-cone under D , which is $\phi \circ \mu = \tau$.

If there exists another factorization $\psi: C \rightarrow T$ of τ by μ . Then it is also a factorization of $\tau * F$ by $\nu = \mu * F$ and thus $\psi = \phi$.

Conversely, assume $\varinjlim D = \mu: D \Rightarrow \Delta_C$. Any co-cone under $D \circ F$ can be uniquely extended to a co-cone under D , then the unique factorization follows and $\mu * F$ is a colimit of $D \circ F$.

2 \Rightarrow 6. For an arbitrary $j_0 \in \text{ob } \mathcal{J}$. Let D be the functor $j \mapsto \text{Hom}_{\mathcal{J}}(j_0, j)$, then $\varinjlim D \circ F = \varinjlim D$. We only need to check that $\varinjlim D$ is a singleton. Indeed, for any $f \in \text{Hom}_{\mathcal{J}}(j_0, j)$, we have $f \circ 1_{j_0} = f$. Consider the functions

$$\text{Hom}(j_0, j_0) \xrightarrow{f_*} \text{Hom}(j_0, j) \rightarrow \varinjlim D$$

One can see that the image of f in $\varinjlim D$ should be the image of 1_{j_0} and thus $\varinjlim D$ is a singleton.

6 \Leftrightarrow 1. Since $\varinjlim_{i \in \text{ob } \mathcal{I}} \text{Hom}_{\mathcal{J}}(j, F(i))$ is a quotient set of the disjoint union of those $\text{Hom}_{\mathcal{J}}(j, F(i))$ and two objects $j \rightarrow F(i)$ and $j \rightarrow F(i')$ are in the same equivalent class if they are connected by a zigzag of morphisms in $(j \downarrow F)$, the cardinal of $\varinjlim_{i \in \text{ob } \mathcal{I}} \text{Hom}_{\mathcal{J}}(j, F(i))$ is the same as the cardinal of the set of connected components in $(j \downarrow F)$. \square

Lemma 2.11.4. *A category \mathcal{I} is connected if and only if $\varinjlim_{\mathcal{I}} \Delta_{\text{Pt}} = \text{Pt}$.*

Proof. Since $\varinjlim_{\mathcal{I}} \Delta_{\text{Pt}}$ is a quotient set of the disjoint union of a family of Pt_i indexed by \mathcal{I} and two objects $x_i \in \text{Pt}_i$ and $x_{i'} \in \text{Pt}_{i'}$ are in the same equivalent class if they are connected by a zigzag of functions between those singletons, the cardinal of $\varinjlim_{\mathcal{I}} \Delta_{\text{Pt}}$ is the same as the cardinal of the set of connected components in \mathcal{I} . \square

Proposition 2.11.5. *If $F: \mathcal{I} \rightarrow \mathcal{J}$ is cofinal then \mathcal{I} is connected if and only if \mathcal{J} is.*

Proof. Let $\Delta_{\text{Pt}}^{\mathcal{I}}: \mathcal{I} \rightarrow \mathbf{Set}$ and $\Delta_{\text{Pt}}^{\mathcal{J}}: \mathcal{J} \rightarrow \mathbf{Set}$ be the constant functors. Then $\Delta_{\text{Pt}}^{\mathcal{I}} = \Delta_{\text{Pt}}^{\mathcal{J}} \circ F$ and thus $\varinjlim \Delta_{\text{Pt}}^{\mathcal{I}} = \varinjlim \Delta_{\text{Pt}}^{\mathcal{J}}$. \square

Proposition 2.11.6. *Let $F: \mathcal{I} \rightarrow \mathcal{J}$ and $G: \mathcal{J} \rightarrow \mathcal{K}$ be two functors.*

1. *If F and G are cofinal, then so is their composite $G \circ F$.*
2. *If F and the composite $G \circ F$ are cofinal, then so is G .*
3. *If G is a fully faithful functor and the composite $G \circ F$ is cofinal, then both functors separately are cofinal.*

Proof. Let $D: \mathcal{K} \rightarrow \mathbf{Set}$ be a functor, then consider the natural functions:

$$\varinjlim D \circ G \circ F \longrightarrow \varinjlim D \circ G \longrightarrow \varinjlim D$$

Then 1, 2 are obvious. For 3, since G is fully faithful, we have $(j \downarrow F) \simeq (G(j) \downarrow G \circ F)$. The latter comma category is connected since $G \circ F$ is cofinal, thus F is cofinal and the result follows from 2. \square

Example 2.11.7. If \mathcal{I} has a terminal object then the functor $F: \mathbf{1} \rightarrow \mathcal{I}$ that picks that terminal object is cofinal: for every $i \in \text{ob } \mathcal{I}$ the comma category $(i \downarrow F)$ is equivalent to $\mathbf{1}$. The converse is also true: if a functor $\mathbf{1} \rightarrow \mathcal{I}$ is cofinal, then its image is a terminal object.

In this case the statement about preservation of colimits states that the colimit over a category with a terminal object is the value of the diagram at that object. Which is also readily checked directly.

Definition 2.11.8. A subcategory \mathcal{I} of \mathcal{J} is said to be **cofinal** if the inclusion functor is cofinal.

A useful sufficient condition is

Proposition 2.11.9. *A full subcategory \mathcal{I} of \mathcal{J} is cofinal if for any $j \in \mathcal{J}$, there exists an arrow $j \rightarrow i$ such that $i \in \mathcal{I}$.*

Corollary 2.11.10. *If \mathcal{I} has a terminal object 1 , then the $\{1\}$ itself is a cofinal subcategory of \mathcal{I} .*

Corollary 2.11.11. *If \mathcal{I} has a terminal object 1 , then for any \mathcal{I} -diagram D , $\mu: D \Rightarrow \Delta_{D_1}$ is a colimit of D . Similarly, If \mathcal{I} has a initial object 0 , then for any \mathcal{I} -diagram D , $\mu: \Delta_{D_0} \Rightarrow D$ is a limit of D .*

Definition 2.11.12. A category \mathcal{I} is said to be **cofinally small** if there exists a small category \mathcal{I}_0 and a cofinal functor $\mathcal{I}_0 \rightarrow \mathcal{I}$.

Definition 2.11.13. Two diagrams D, D' in a category \mathcal{C} are said to be **cofinal** if they have equivalent colimits.

Remark. It is often said that two diagrams are cofinal even when neither has a colimit, if they acquire a common colimit on passing to a suitable completion of \mathcal{C} . This can probably be phrased internally to \mathcal{C} , at the cost of intuition.

Exercises

2.19. Let $D: \mathcal{I}^{\text{op}} \rightarrow \mathcal{C}$ be a diagram. The category $\mathbf{Cone}(D)$ has a functor to \mathcal{C} , mapping each cone to its vertex. Prove that D has a limit if and only if this functor has a colimit.

§2.12 Commutativity of limits and colimits

In this section, we consider the following kind of diagram

$$D: \mathcal{I} \times \mathcal{J} \longrightarrow \mathcal{C}$$

If we fix an $i \in \text{ob } \mathcal{I}$, the bifunctor D induces the following diagram:

$$D(i, -): \mathcal{J} \longrightarrow \mathcal{C}$$

Then we can consider its limits and colimits.

A morphism $f: i \rightarrow i'$ in \mathcal{I} induces a natural transformation

$$D(f, -): D(i, -) \Rightarrow D(i', -)$$

and actually defines a functor

$$\begin{aligned} D(f, -)_*: \mathbf{Cone}(D(i, -)) &\longrightarrow \mathbf{Cone}(D(i', -)) \\ \mu &\longmapsto D(f, -) \circ \mu \end{aligned}$$

If the limits of $D(i, -)$ and $D(i', -)$ exist, then $D(f, -)_*$ maps the limit of $D(i, -)$ to a cone over $D(i', -)$, which is equipped with a unique morphism to the limit of $D(i', -)$. Therefore the functor induces a unique factorization:

$$\begin{array}{ccc} \varprojlim_{\mathcal{J}} D(i, -) & \xrightarrow{L_f} & \varprojlim_{\mathcal{J}} D(i', -) \\ \Downarrow & & \Downarrow \\ D(i, -) & \Longrightarrow & D(i', -) \end{array}$$

Notice that since cones are actually natural transformations from constant functors, thus the top row is just a morphism in \mathcal{C} .

If all the functor $D(i, -)$ have limits, then taking limit is a functor $L: \mathcal{I} \rightarrow \mathcal{C}$ which maps object i to $\varprojlim_{\mathcal{J}} D(i, -)$ and arrow f to L_f .

Now, L itself is a diagram of shape \mathcal{I} , thus we can consider its limit and colimit, which are denoted by

$$\varprojlim_{\mathcal{I}} \varprojlim_{\mathcal{J}} D \quad \text{and} \quad \varinjlim_{\mathcal{I}} \varprojlim_{\mathcal{J}} D$$

On the other hand, an analogous reasoning shows that if all the functor $D(i, -)$ have colimits, then taking colimit is a functor $C: \mathcal{I} \rightarrow \mathcal{C}$. Thus we can consider its limit and colimit, which are denoted by

$$\varprojlim_{\mathcal{I}} \varinjlim_{\mathcal{J}} D \quad \text{and} \quad \varinjlim_{\mathcal{I}} \varprojlim_{\mathcal{J}} D$$

Similarly, we can begin with fixing a $j \in \mathcal{J}$ and do the same things. Then we have the following mixed limits and colimits

$$\varprojlim_{\mathcal{J}} \varprojlim_{\mathcal{I}} D \quad \varinjlim_{\mathcal{J}} \varinjlim_{\mathcal{I}} D \quad \varprojlim_{\mathcal{J}} \varinjlim_{\mathcal{I}} D \quad \varinjlim_{\mathcal{J}} \varprojlim_{\mathcal{I}} D$$

Here the question follows: what is the relationship of these limits and colimits listed above ?

Interchange property

Proposition 2.12.1. *Consider a complete category \mathcal{C} and two small categories \mathcal{I}, \mathcal{J} . Given a functor $D: \mathcal{I} \times \mathcal{J} \rightarrow \mathcal{C}$ and using the previous notations, the following interchange property holds:*

$$\varprojlim_{\mathcal{I}} \varprojlim_{\mathcal{J}} D \cong \varprojlim_{\mathcal{J}} \varprojlim_{\mathcal{I}} D$$

Proof. We construct some canonical morphisms and show that they are isomorphisms. Then the require property follows.

Notice that an arrow $(i, j) \rightarrow (i', j')$ in $\mathcal{I} \times \mathcal{J}$ consists of an arrow $i \rightarrow i'$ in \mathcal{I} and an arrow $j \rightarrow j'$ in \mathcal{J} , that the limit $\varprojlim_{\mathcal{I}} \varprojlim_{\mathcal{J}} D$ is a cone over those $\varprojlim_{\mathcal{J}} D(i, -)$ while each of them is a cone over those $D(i, j)$ with i fixed and that the similar fact holds for $\varprojlim_{\mathcal{J}} \varprojlim_{\mathcal{I}} D$. We have the following commutative diagram

$$\begin{array}{ccccc}
 & & \nu' \dashrightarrow & \varprojlim_{\mathcal{J}} \varprojlim_{\mathcal{I}} D & \\
 & & \downarrow \nu & \downarrow & \searrow \\
 & \mu' \dashrightarrow & \varprojlim_{\mathcal{I} \times \mathcal{J}} D & \dashrightarrow & \varprojlim_{\mathcal{I}} D(-, j) \longrightarrow \varprojlim_{\mathcal{I}} D(-, j') \\
 & \downarrow \mu & \downarrow & \downarrow & \downarrow \\
 \varprojlim_{\mathcal{I}} \varprojlim_{\mathcal{J}} D & \longrightarrow & \varprojlim_{\mathcal{J}} D(i, -) & \longrightarrow & D(i, j) \longrightarrow D(i, j') \\
 & \searrow & \downarrow & \downarrow & \downarrow \\
 & & \varprojlim_{\mathcal{J}} D(i', -) & \longrightarrow & D(i', j) \longrightarrow D(i', j')
 \end{array}$$

Then we can see that both $\varprojlim_{\mathcal{I}} \varprojlim_{\mathcal{J}} D$ and $\varprojlim_{\mathcal{J}} \varprojlim_{\mathcal{I}} D$ are cones over D thus there exist unique factorizations μ and ν respectively. Those are our require canonical morphisms.

On the other hand, for any fixed i , the limit $\varprojlim_{\mathcal{I} \times \mathcal{J}} D$ is a cone over $D(i, -)$, thus the unique factorization exists. Moreover, this factorization commute with the morphisms between those $D(i, -)$ and make $\varprojlim_{\mathcal{I} \times \mathcal{J}} D$ to be a cone over L , which ensure that there exists a unique factorization μ' . Similarly, a unique factorization ν' .

It is easy to check that μ' and ν' are the inverse of μ and ν respectively, thus μ and ν are isomorphisms.

To see the naturality, consider another diagram D' of shape $\mathcal{I} \times \mathcal{J}$ and a natural transformation α between D and D' . Then we have a similar commutative diagram for D' as above one and the lower right squares are connected by α . Then use the universal properties of limits, it is easy to see that α provides a corresponding of those diagrams and the naturality follows. \square

Example 2.12.2.

$$\prod_i \left(\prod_j D_{i,j} \right) \approx \prod_j \left(\prod_i D_{i,j} \right)$$

Example 2.12.3.

$$\ker \left(\prod_i f_i, \prod_i g_i \right) \approx \prod_i \ker(f_i, g_i)$$

Filtered colimits commute with finite limits

Now we consider the mixed interchange property for

$$\varinjlim_{\mathcal{I}} \varprojlim_{\mathcal{J}} D \quad \text{and} \quad \varprojlim_{\mathcal{J}} \varinjlim_{\mathcal{I}} D$$

However, it is easy to see that the mixed interchange property does not hold in general. For instance, consider the following mixed interchange property

$$(A \times B) \sqcup (C \times D) \approx (A \sqcup B) \times (C \sqcup D)$$

It is easy to see that it is false just by a cardinality argument.

Now there is a very important case in which the mixed interchange property holds in **Set**: this is the case where \mathcal{I} is filtered and \mathcal{J} is finite.

Definition 2.12.4. A **filtered category** is a category \mathcal{C} in which every finite diagram has a cocone.

This can be rephrased in more elementary terms by saying that

Proposition 2.12.5. *A category \mathcal{C} is filtered if and only if*

1. \mathcal{C} is not empty.
2. For any two objects $A, B \in \text{ob } \mathcal{C}$, there exists an object $C \in \text{ob } \mathcal{C}$ and morphisms $A \rightarrow C$ and $B \rightarrow C$.
3. For any two parallel morphisms $f, g: A \rightarrow B$ in \mathcal{C} , there exists a morphism $h: B \rightarrow C$ such that $h \circ f = h \circ g$.

Proof. Just as all finite colimits can be constructed from initial objects, binary coproducts, and coequalizers, so a cocone on any finite diagram can be constructed from these three.

In deed, whenever there is two objects in the diagram, we can apply *b*) to find an object under them, if there is an arrow between them, we can then apply *c*) to treat the triangle commutative. After this surgery, we get a smaller diagram such that a co-cone under the original diagram is a co-cone under it. Since we consider finite diagrams, after finitely many steps, we get an object, which is a require co-cone. \square

Example 2.12.6. A directed poset (or filtered poset, it depends on how you view the order as arrows) is a filtered category.

Example 2.12.7. Filtered categories are not necessarily small, or even not essentially small. For example, the category of all ordinals is filtered and not essentially small.

Example 2.12.8. Every category with a terminal object is filtered.

Example 2.12.9. Every category which has finite colimits is filtered.

Example 2.12.10. A product of filtered categories is filtered.

Recall that the colimit of a diagram D in the category **Set** is given by a quotient set

$$\varinjlim D = (\bigsqcup_{i \in \text{ob } \mathcal{I}} D_i) / \sim$$

where the equivalence relation \sim is that which is generated by

$$\{(x \in D_i) \sim (x' \in D_{i'}) \mid \exists (f: i \rightarrow i') \text{ s.t. } (D_f(x) = x')\}$$

If the index category \mathcal{I} is filtered, then the equivalence relation \sim can be write down explicitly

$$(x \in D_i) \sim (x' \in D_{i'}) \text{ if } \exists (f: i \rightarrow i'', g: i' \rightarrow i'') \text{ s.t. } (D_f(x) = D_g(x'))$$

This gives a very easy description of colimits in **Set** and allowed us to write down the mixed interchange property in **Set** explicitly.

Theorem 2.12.11. *Consider a filtered category \mathcal{I} and a finite category \mathcal{J} . Given a functor $D: \mathcal{I} \times \mathcal{J} \rightarrow \mathbf{Set}$, the following mixed interchange property holds:*

$$\varinjlim_{\mathcal{I}} \varprojlim_{\mathcal{J}} D \cong \varprojlim_{\mathcal{J}} \varinjlim_{\mathcal{I}} D$$

Proof. First of all, we construct the canonical morphism between them. Consider the following commutative diagram

$$\begin{array}{ccccc}
 \varprojlim_{\mathcal{J}} D(i, -) & \longrightarrow & D(i, j) & \longrightarrow & D(i, j') \\
 \swarrow & & \downarrow & & \downarrow \\
 \varinjlim_{\mathcal{I}} \varprojlim_{\mathcal{J}} D & \longleftarrow & \varprojlim_{\mathcal{J}} D(i', -) & \longrightarrow & D(i', j) & \longrightarrow & D(i', j') \\
 & & \downarrow & & \downarrow & & \downarrow \\
 & & \varinjlim_{\mathcal{I}} D(-, j) & \longrightarrow & \varinjlim_{\mathcal{I}} D(-, j') \\
 & \nearrow \lambda & \uparrow & & \nearrow \\
 & & \varprojlim_{\mathcal{J}} \varinjlim_{\mathcal{I}} D & &
 \end{array}$$

It is easy to see that each $\varprojlim_{\mathcal{J}} D(i, -)$ is a cone over those $\varinjlim_{\mathcal{I}} D(-, j)$ and thus there exists a unique factorization from it to $\varprojlim_{\mathcal{J}} \varinjlim_{\mathcal{I}} D$. Consider these factorizations for all $\varprojlim_{\mathcal{J}} D(i, -)$, it is easy to check that $\varprojlim_{\mathcal{J}} \varinjlim_{\mathcal{I}} D$ is a co-cone under them. Thus the unique factorization λ exists.

Moreover, this diagrammatic construction ensure that the canonical morphism is natural.

But, as we have seen in the beginning of this subsection, the canonical morphism is not an isomorphism in general. So we need to write down it explicitly in our cases.

Recall that, in **Set**, the limit $\varprojlim_{\mathcal{J}} D(i, -)$ is given by

$$L_i = \{(x_j)_{j \in \text{ob } \mathcal{J}} \mid x_j \in D(i, j); D(i, f)(x_j) = x_{j'}, \forall f: j \rightarrow j'\}$$

Thus

$$\varprojlim_{\mathcal{I}} \varprojlim_{\mathcal{J}} D = (\bigsqcup_{i \in \text{ob } \mathcal{I}} L_i) / \sim$$

Where the equivalence relation \sim is given by

$$\begin{aligned} ((x_j)_{j \in \text{ob } \mathcal{J}} \in L_i) \sim ((y_j)_{j \in \text{ob } \mathcal{J}} \in L_{i'}) \quad & \text{if} \\ \exists (f: i \rightarrow i'', g: i' \rightarrow i'') \text{ s.t. } & (\forall j \in \text{ob } \mathcal{J}) (D(f, j)(x_j) = D(g, j)(y_j)) \end{aligned}$$

Similarly,

$$\varprojlim_{\mathcal{J}} \varinjlim_{\mathcal{I}} D = \{([x_j])_{j \in \text{ob } \mathcal{J}} \mid x_j \in C_j; C_f([x_j]) = [x_{j'}], \forall f: j \rightarrow j'\}$$

Where

$$C_j = (\bigsqcup_{i \in \text{ob } \mathcal{I}} D(i, j) / \sim_j \quad C_f = [D(i, f)]$$

and the equivalence relation \sim_j is given by

$$\begin{aligned} (x \in D(i, j)) \sim_j (y \in D(i', j)) \quad & \text{if} \\ \exists (f: i \rightarrow i'', g: i' \rightarrow i'') \text{ s.t. } & (D(f, j)(x) = D(g, j)(y)) \end{aligned}$$

Use these explicit descriptions above, it is not difficult to verify that the canonical morphism λ is given by

$$\lambda([(x_j)_{j \in \text{ob } \mathcal{J}}]) = ([x_j])_{j \in \text{ob } \mathcal{J}}$$

Now we prove it is bijective.

Let us prove first that λ is injective. Consider $(x_j)_{j \in \text{ob } \mathcal{J}} \in L_i$ and $(y_j)_{j \in \text{ob } \mathcal{J}} \in L_{i'}$ such that $[x_j] = [y_j]$ for every $j \in \text{ob } \mathcal{J}$. We need to show that $[(x_j)_{j \in \text{ob } \mathcal{J}}] = [(y_j)_{j \in \text{ob } \mathcal{J}}]$.

For each $j \in \text{ob } \mathcal{J}$, $[x_j] = [y_j]$ means there exists arrows $f_j: i \rightarrow i_j$ and $g_j: i' \rightarrow i_j$ such that $D(f_j, j)(x_j) = D(g_j, j)(y_j)$. For these f_j and g_j , since \mathcal{I} is filtered, we can find two composite morphisms $f: i \rightarrow i''$ and $g: i' \rightarrow i''$ such that $D(f, j)(x_j) = D(g, j)(y_j)$ for all $j \in \text{ob } \mathcal{J}$. Which is that $[(x_j)_{j \in \text{ob } \mathcal{J}}] = [(y_j)_{j \in \text{ob } \mathcal{J}}]$.

Let us now prove that λ is surjective. Consider $([x_j])_{j \in \text{ob } \mathcal{J}}$ in the right set, we need to show that there exist $[(y_j)_{j \in \text{ob } \mathcal{J}}]$ in the left set such that $x_j \sim_j y_j$ for every $j \in \text{ob } \mathcal{J}$.

For those $x_j \in D(i_j, j)$, since \mathcal{I} is filtered, we can find morphisms $f_j: i_j \rightarrow i$ with common target. Then we have $D(f_j, j)(x_j) \sim_j x_j$ for every $j \in \text{ob } \mathcal{J}$. But this does not mean that $(D(f_j, j)(x_j))_{j \in \text{ob } \mathcal{J}}$ lies in L_i .

Since $([x_j])_{j \in \text{ob } \mathcal{J}} \in \varprojlim_{\mathcal{J}} \varinjlim_{\mathcal{I}} D$, we have $C_d([x_j]) = [x_{j'}]$ for every $d: j \rightarrow j'$. Which means $D(i_j, d)(x_j) \sim_{j'} x_{j'}$ and thus $D(f_j, d)(x_j) \sim_{j'} D(f_{j'}, j)(x_{j'})$. Which means there exists arrows $g_d, h_d: i \rightarrow i_d$ such that

$$D(g_d \circ f_j, d)(x_j) = D(h_d \circ f_{j'}, j)(x_{j'})$$

Consider the diagram constituted of all the morphisms g_d, h_d in \mathcal{I} , we then find a single morphism $k: i \rightarrow i'$ such that

$$D(k \circ f_j, d)(x_j) = D(k \circ f_{j'}, j)(x_{j'})$$

for all arrows d . Therefore the family $(D(k \circ f_j, j)(x_j))_{j \in \text{ob } \mathcal{J}}$ lies in L_i and its equivalence class is still mapped by λ to $([x_j])_{j \in \text{ob } \mathcal{J}}$. \square

Remark. This proof is due to [Bor08]. I recognize that it is very technical (but not difficult), but I don't have a soft one.

The mixed interchange property in **Set** is the crucial property of filtered colimits.

Proposition 2.12.12. *Let \mathcal{I} be a small category. Then the following are equivalent:*

1. \mathcal{I} is filtered;
2. colimits under \mathcal{I} commute with finite limits in **Set**.
3. the diagonal functor $\Delta: \mathcal{I} \rightarrow [\mathcal{J}, \mathcal{I}]$ is cofinal for every finite category \mathcal{J} .

Proof. $a) \Rightarrow b)$ is just Theorem 2.12.11. To show $b) \Rightarrow a)$, we check the conditions in Proposition 2.12.5.

Since the finite limit $\varprojlim \text{Pt}$ is not always a singleton while a colimit of empty diagram in **Set** is always a singleton, \mathcal{I} must be nonempty.

For any $1, 2 \in \text{ob } \mathcal{I}$, consider the discrete diagram $\{\text{Hom}(j, i)\}_{j=1,2; i \in \text{ob } \mathcal{I}}$. Then we have

$$\varinjlim_{\mathcal{I}} (\text{Hom}(1, i) \times \text{Hom}(2, i)) \approx (\varinjlim_{\mathcal{I}} \text{Hom}(1, i)) \times (\varinjlim_{\mathcal{I}} \text{Hom}(2, i))$$

The components of right hand are singletons, thus so is the left hand. Hence there exists some $i \in \text{ob } \mathcal{I}$ such that $\text{Hom}(1, i) \times \text{Hom}(2, i)$ is nonempty.

For any arrows $f, g: 1 \rightarrow 2$ in \mathcal{I} , consider the diagram consisting of objects $\{\text{Hom}(j, i)\}_{j=1,2; i \in \text{ob } \mathcal{I}}$ and functions $f_i, g_i: \text{Hom}(2, i) \rightarrow \text{Hom}(1, i)$ for every $i \in \text{ob } \mathcal{I}$. Then we have

$$\varinjlim_{\mathcal{I}} \ker(f_i, g_i) \approx \ker(\varinjlim_{\mathcal{I}} f_i, \varinjlim_{\mathcal{I}} g_i)$$

The right hand is a singleton, thus there exist some i such that $\ker(f_i, g_i)$ is nonempty.

$$\begin{array}{ccc} \begin{array}{|c|} \hline \Delta_i \\ \hline \end{array} & & \\ \begin{array}{|c|} \hline D \\ \hline \end{array} & \begin{array}{c} \nearrow \\ \searrow \end{array} & \begin{array}{|c|} \hline \Delta_{i'} \\ \hline \end{array} \\ \Rightarrow & & \Rightarrow \end{array}$$

$c) \Rightarrow a)$ is obvious. For $a) \Rightarrow c)$, let \mathcal{J} be a finite category, for any $D \in \text{ob}[\mathcal{J}, \mathcal{I}]$, there exists a co-cone $D \Rightarrow \Delta_i$, thus $(D \downarrow \Delta)$ is nonempty. To see it is connected, consider two co-cone $D \Rightarrow \Delta_i$ and $D \Rightarrow \Delta_{i'}$, then the commutative diagrams in them form a new diagram $D^+: \mathcal{J}^+ \rightarrow \mathcal{I}$, thus there exists a co-cone $D^+ \Rightarrow \Delta_{i''}$. But there exists a inclusion $\mathcal{J} \rightarrow \mathcal{J}^+$, then we get a co-cone $D \Rightarrow D^+ \Rightarrow \Delta_{i''}$, which connects $D \Rightarrow \Delta_i$ and $D \Rightarrow \Delta_{i'}$. \square

Example 2.12.13. In **Set**, consider a set X and the diagram \mathcal{I} constituted of the finite subsets of X and the canonical inclusions between them. This diagram is filtered and the filtered colimit of it is obviously X .

Example 2.12.14. A poset is a filtered category. Particularly, a series indexed by natural numbers is a filtered diagram, thus its colimit can be interchanged with finite limits.

Definition 2.12.15. A category is said to be **cofiltered** if its opposite is filtered.

Sifted colimits commute with finite products

Definition 2.12.16. A category \mathcal{I} is called **sifted** if colimits of diagrams of shape \mathcal{I} (called **sifted colimits**) commute with finite products in **Set**.

Example 2.12.17. Every filtered category is sifted.

Since any n -ary product ($n \geq 2$) can be constructed from binary products, we have

Proposition 2.12.18. *A category \mathcal{I} is sifted if and only if colimits of \mathcal{I} -diagrams commute with nullary products and binary products.*

Like filtered category, we have the following proposition.

Proposition 2.12.19. *A small category \mathcal{I} is sifted if and only if it is nonempty and the diagonal functor $\Delta: \mathcal{I} \rightarrow \mathcal{I} \times \mathcal{I}$ is cofinal.*

Proof. For any two objects i, i' in \mathcal{I} , the diagonal functor $\Delta: \mathcal{I} \rightarrow \mathcal{I} \times \mathcal{I}$ is cofinal implies that there exists a cospan $i \rightarrow i'' \leftarrow i'$. Therefore the condition

“ \mathcal{I} is nonempty and the diagonal functor Δ is cofinal”

is equivalent to the condition

“ \mathcal{I} is connected and the diagonal functor Δ is cofinal”.

1, \mathcal{I} is connected if and only if colimits of \mathcal{I} -diagrams commute with nullary products. Indeed, a nullary products is just the terminal object Pt , thus the commutativity means $\varinjlim_{\mathcal{I}} \text{Pt} \approx \text{Pt}$, which is equivalent to say that \mathcal{I} is connected by Lemma 2.11.4.

2, The diagonal functor Δ is cofinal if and only if colimits of \mathcal{I} -diagrams commute with binary products. Indeed, If D, D' are two \mathcal{I} -diagrams, then we have the following commutative diagram

$$\begin{array}{ccc} \varinjlim (D_i \times D'_i) & \longrightarrow & (\varinjlim D) \times (\varinjlim D') \\ \parallel & & \uparrow \approx \\ \varinjlim (D \times D') \circ \Delta & \longrightarrow & \varinjlim D \times D' \end{array}$$

Then the upper morphism is an isomorphism if and only if so is the bottom, which is equivalent to say that the diagonal functor Δ is cofinal by Theorem 2.11.3. \square

Corollary 2.12.20. *Every category having finite coproducts is sifted.*

Proof. Since a category having finite coproducts is nonempty (it has an initial object) and each category of cospanns has an initial object (the coproduct) thus connected. \square

Coproducts commute with connected limits

Proposition 2.12.21. *Let \mathcal{I} be a discrete small category, \mathcal{J} a connected category and $D: \mathcal{I} \times \mathcal{J} \rightarrow \mathbf{Set}$ a functor. Then the canonical function*

$$\coprod_{\mathcal{I}} \varprojlim_{\mathcal{J}} D(i, j) \longrightarrow \varprojlim_{\mathcal{J}} \coprod_{\mathcal{I}} D(i, j)$$

is bijective.

Proof. We have

$$\begin{aligned} \varprojlim_{\mathcal{J}} D(i, j) &= \{(x_j)_{j \in \text{ob } \mathcal{J}} \mid x_j \in D(i, j); D(i, f)(x_j) = x_{j'}, \forall f: j \rightarrow j'\} \\ \varprojlim_{\mathcal{J}} \coprod_{\mathcal{I}} D(i, j) &= \{(x_j)_{j \in \text{ob } \mathcal{J}} \mid x_j \in \coprod_{\mathcal{I}} D(i, j); (*)\} \end{aligned}$$

where the condition $(*)$ is

for every $f: j \rightarrow j'$, we have $D(i, f)(x_j) = x_{j'}$ for some i .

When \mathcal{J} is connected, this condition require all the components of an element in $\varprojlim_{\mathcal{J}} \coprod_{\mathcal{I}} D(i, j)$ must be in the same $\varprojlim_{\mathcal{J}} D(i, j)$ for some i , which implies the canonical function is bijective. \square

Universality of colimits

Let \mathcal{C} be a category having pullbacks and colimits of shape \mathcal{I} .

Let B be a colimit object of some \mathcal{I} -diagram D , then for any \mathcal{C} -morphism $f: A \rightarrow B$, consider the following pullback diagram

$$\begin{array}{ccc} f^*D & \Rightarrow & D \\ \Downarrow & & \Downarrow \\ A & \xrightarrow{f} & B \end{array}$$

Since taking pullback along f is a functor from \mathcal{C}/B to \mathcal{C}/A , the left is then a co-cone under f^*D .

Use this notation, we define

Definition 2.12.22. A colimit is said to be **universal** if it is preserved under pullback. That means the pullback of it along any morphism is again a colimit.

Remark. We say that colimits of shape \mathcal{I} are **stable by base change** or **stable under pullback** if for every \mathcal{I} -diagram D , its colimit is universal.

Theorem 2.12.23. *In \mathbf{Set} , small colimits are universal.*

Proof. Since any small colimit can be constructed from coproducts and coequalizers, it suffices to prove the result separately for them.

Let $\{B_i\}_{i \in I}$ be a set of sets, their coproduct is just the disjoint union $B = \bigsqcup_I B_i$. Consider an arbitrary function $f: A \rightarrow B$ and the cartesian diagram

$$\begin{array}{ccc} A_i & \longrightarrow & B_i \\ \downarrow & & \downarrow \\ A & \xrightarrow{f} & B \end{array}$$

Then, by simple compute, we get

$$A_i = \{(a, f(a)) \mid a \in A, f(a) \in B_i\} \approx \{a \in A \mid f(a) \in B_i\}$$

And thus $A \approx \bigsqcup_I A_i$.

Let $f, g: S \rightarrow T$ be two parallel functions and (Q, q) is their coequalizer. Consider an arbitrary function $h: P \rightarrow Q$ and the pullback diagram along

h

$$\begin{array}{ccc}
S' & \xrightarrow{h''} & S \\
f' \downarrow & & \downarrow f \\
& g' & g \\
T' & \xrightarrow{h'} & T \\
p \downarrow & & \downarrow q \\
P & \xrightarrow{h} & Q
\end{array}$$

Then $p \circ f' = p \circ g'$ and f', g' are pullbacks of f, g along h' respectively (by Proposition 2.6.8).

Since q is surjective, so is p , thus we can regard P as a quotient set of T' by the equivalence relation R :

$$xRy \iff p(x) = p(y)$$

Then we need to show that R is generated by $R_0 = \{(f'(s'), g'(s')) \mid s' \in S'\}$.

Since $p \circ f' = p \circ g'$, R contains R_0 . Conversely, consider two elements $x, y \in T'$ such that $p(x) = p(y)$. Then

$$q \circ h'(x) = h \circ p(x) = h \circ p(y) = q \circ h'(y)$$

Since $(Q, q) = \text{coker}(f, g)$, $(h'(x), h'(y))$ is contained in the equivalence relation generated by $\{(f(s), g(s)) \mid s \in S\}$. Thus R is contained in the equivalence relation generated by its inverse image in along h' . Denote this inverse image by R_1 , then we only need to show R_1 is contained in R_0 .

Indeed, for any $(x, y) \in R_1$, there exists a $s \in S$ such that

$$f(s) = h'(x), g(s) = h'(y)$$

But the upper two squares are cartesian, so there exists a $s' \in S'$ such that

$$f'(s') = x, g'(s') = y, h''(s') = s$$

Thus $(x, y) \in R_0$. □

The universality of colimits is a very peculiar property which is much less common than to be filtered.

Exercises

2.20. Prove the interchange property for colimits.

2.21. Construct the colimit of a filtered diagram in **Set** explicitly.

§2.13 Limits and colimits in functor categories

Limits in functor categories are computed pointwise.

Proposition 2.13.1. *Consider categories $\mathcal{I}^{\text{op}}, \mathcal{A}, \mathcal{B}$, with \mathcal{I}^{op} and \mathcal{A} small. Let $D: \mathcal{I}^{\text{op}} \rightarrow [\mathcal{A}, \mathcal{B}]$ be a functor. If for every \mathcal{A} -object A the functor $D(-)(A): \mathcal{I}^{\text{op}} \rightarrow \mathcal{B}$ has a limit, then D has a limit as well and this limit is computed pointwise.*

Proof. Recall that $[\mathcal{I}^{\text{op}}, [\mathcal{A}, \mathcal{B}]] \simeq [\mathcal{A}, [\mathcal{I}^{\text{op}}, \mathcal{B}]]$ (see 1.3), this is the crucial fact we used in the proof.

For any $A \in \text{ob } \mathcal{A}$, let $\mu_A: \Delta_{L_A} \Rightarrow D(-)(A)$ be the limit of $D(-)(A)$. For any morphism $f: A \rightarrow A'$, since D is a functor from \mathcal{I} to $[\mathcal{A}, \mathcal{B}]$, it induces a natural transformation $\phi_f: D(-)(A) \Rightarrow D(-)(A')$. It is easy to see that $\phi_f \circ \mu_A$ is also a cone over $D(-)(A')$, thus there exists a unique morphism $L_f: A \rightarrow A'$ making the following diagram commute

$$\begin{array}{ccc} L_A & \xRightarrow{\mu_A} & D(-)(A) \\ L_f \downarrow & & \Downarrow \phi_f \\ L_{A'} & \xRightarrow{\mu_{A'}} & D(-)(A') \end{array}$$

Therefore the above data define a functor $L: \mathcal{A} \rightarrow \mathcal{B}$ mapping object A to L_A and morphism f to L_f . This functor can also be view as a functor from \mathcal{A} to $[\mathcal{I}^{\text{op}}, \mathcal{B}]$ mapping A to Δ_{L_A} . Then the above data define a natural transformation from such functor to D viewed as a functor from \mathcal{A} to $[\mathcal{I}^{\text{op}}, \mathcal{B}]$. Then, by interchange variables, we get a cone $\mu: \Delta_L \Rightarrow D$.

To show μ is a limit of D , we consider another cone $\tau: \Delta_T \Rightarrow D$. By interchange variables, we get a natural transformation and apply to $f: A \rightarrow A'$, we get the following commutative diagram

$$\begin{array}{ccc} T_A & \xRightarrow{\tau_A} & D(-)(A) \\ T_f \downarrow & & \Downarrow \phi_f \\ T_{A'} & \xRightarrow{\tau_{A'}} & D(-)(A') \end{array}$$

For each object A , τ_A is a cone over $D(-)(A)$, thus there exists a unique factorization $\alpha_A: T_A \rightarrow L_A$ of τ_A by μ_A . Then it is not difficult to check

the commutativity of the following diagram

$$\begin{array}{ccc} T_A & \xrightarrow{\alpha_A} & L_A \\ T_f \downarrow & & \downarrow L_f \\ T_{A'} & \xrightarrow{\alpha_{A'}} & L_{A'} \end{array}$$

Thus α is a natural transformation from T to L and then the unique factorization between Δ_T and Δ_L follows. \square

As an immediate corollary we get

Theorem 2.13.2. *If \mathcal{A} is small and \mathcal{B} is complete, then $[\mathcal{A}, \mathcal{B}]$ is complete and its limits are computed pointwise. Similarly, if \mathcal{B} is cocomplete, then $[\mathcal{A}, \mathcal{B}]$ is cocomplete and its colimits are computed pointwise,*

Corollary 2.13.3. *Consider a small category \mathcal{C} . Then we have:*

1. $\mathbf{PSh}(\mathcal{C})$ is complete and cocomplete.
2. In $\mathbf{PSh}(\mathcal{C})$, filtered colimits commute with finite limits.
3. In $\mathbf{PSh}(\mathcal{C})$, sifted colimits commute with finite products
4. In $\mathbf{PSh}(\mathcal{C})$, coproducts commute with connected limits
5. In $\mathbf{PSh}(\mathcal{C})$, colimits are universal.

Proof. By Theorem 2.13.2 and results in the previous section. \square

Corollary 2.13.4. *If \mathcal{C} is a small category. Then the Yoneda embedding $\Upsilon: \mathcal{C} \longrightarrow \mathbf{PSh}(\mathcal{C})$ preserves limits.*

Remark. The Yoneda embedding does not in general preserve colimits.

Theorem 2.13.5. *Let \mathcal{C} be a small category and $D: \mathcal{C}^{\text{op}} \rightarrow \mathbf{Set}$ a presheaf. In $\mathbf{PSh}(\mathcal{C})$, D can be presented as the colimit of a diagram just constituted of representable functors and representable natural transformations.*

Proof. Consider the composite functor

$$\mathbf{Els}(D)^{\text{op}} \xrightarrow{\phi_D} \mathcal{C} \xrightarrow{\Upsilon} \mathbf{PSh}(\mathcal{C})$$

where $\mathbf{Elts}(D)$ is the category of elements of D defined in Example 1.8.7 and ϕ_D is the opposite of the forgetful functor. The its diagram is constituted of representable functors and representable natural transformations. We claim that D is the colimit of it.

The crucial fact we used in the proof is that for any presheaf F , the natural transformation $\alpha: \text{Hom}(-, X) \Rightarrow F$ is uniquely determined by the object $F(X)$ and the element $\alpha_X(1_X)$.

Use this fact, it is easy to see that D is a co-cone under $\Upsilon \circ \phi_D$. Moreover, Let $\Phi: \Upsilon \circ \phi_D \Rightarrow \Delta_T$ be an arbitrary co-cone, $\Phi_{(D(X), x)}: \text{Hom}(-, X) \Rightarrow T$ is uniquely determined by $T(X)$ and $\Phi_{(D(X), x)}(1_X)$. Then we get a natural transformation $\alpha: D \rightarrow T$ whose component is given by

$$\begin{aligned}\alpha_X: D(X) &\longrightarrow T(X) \\ x &\longmapsto \Phi_{(D(X), x)}(1_X)\end{aligned}$$

It is not difficult to check it is the required unique factorization. \square

Example 2.13.6. The category $[\mathcal{A}, \mathcal{B}]$ can be complete even when \mathcal{B} is not. An obvious example is obtained by taking \mathcal{A} and \mathcal{B} to be empty: \mathcal{B} is not complete or cocomplete, since it does not have a terminal or an initial object. But $[\mathcal{A}, \mathcal{B}]$ is the category with just one single object (the empty functor) and the identity on it; that category is obviously both complete and cocomplete. And since \mathcal{A} doesn't have any object, limits in $[\mathcal{A}, \mathcal{B}]$ are still pointwise!

Exercises

2.22. If \mathcal{A} is small and \mathcal{B} is complete, then a natural transformation α in $[\mathcal{A}, \mathcal{B}]$ is monic if and only if its every component is monic.

2.23. Consider the category $\mathbf{2}$ with two objects $0, 1$ and one single non-identity arrow $0 \rightarrow 1$. Find a category \mathcal{C} and two functors from $\mathbf{2}$ to \mathcal{C} such that their product exists but is not pointwise. [Hint: find a poset.]

§2.14 Limits and colimits in comma categories

Proposition 2.14.1. *Consider two complete categories \mathcal{A}, \mathcal{B} and two continuous functors $F: \mathcal{A} \rightarrow \mathcal{C}, G: \mathcal{B} \rightarrow \mathcal{C}$, then the comma category $(F \downarrow G)$ is complete and the domain functor $U: (F \downarrow G) \rightarrow \mathcal{A}$ and codomain functor $V: (F \downarrow G) \rightarrow \mathcal{B}$ are continuous.*

Proof. Let $D: \mathcal{I}^{\text{op}} \rightarrow (F \downarrow G)$ be a small diagram. We construct its limit by the limits of $U \circ D$ and $V \circ D$, thus the statement follows.

Assume $\mu: \Delta_A \rightarrow U \circ D$ and $\nu: \Delta_B \rightarrow V \circ D$ are limits of $U \circ D$ and $V \circ D$ respectively. Since F, G are continuous, $F * \mu$ and $G * \nu$ are limits of $F \circ U \circ D$ and $G \circ V \circ D$ respectively. On the other hand, there is a natural transformation $\alpha: F \circ U \Rightarrow G \circ V$, so we get the factorization $h: F(A) \rightarrow G(B)$ making the following diagram commute:

$$\begin{array}{ccc} F(A) & \xRightarrow{F*\mu} & F \circ U \circ D \\ h \downarrow & & \Downarrow \alpha * D \\ G(B) & \xRightarrow{G*\nu} & G \circ V \circ D \end{array}$$

By the universal property of comma category, the both vertical data form a functor from \mathcal{I}^{op} to $(F \downarrow G)$ and the horizontal data form a natural transformation $\eta: \Delta_{(A,h,B)} \Rightarrow D$. It is now straightforward to check that η is the limit of D . \square

Corollary 2.14.2. *Let \mathcal{C} be a small category and $F: \mathcal{C} \rightarrow \mathbf{Set}$ a continuous functor, then $\mathbf{Elts}(F)$ is complete and the forgetful functor $\mathbf{Elts}(F) \rightarrow \mathcal{C}$ is continuous.*

Let's consider slider categories. It should be noticed that the constant functor Δ_I does not, in general, preserve limits or colimits. Indeed in **1** one has $* \times * = *$ and $* \amalg * = *$, but generally $I \times I \neq I$ and $I \amalg I \neq I$. Nevertheless we have the following result.

Proposition 2.14.3. *Consider a category \mathcal{C} and a fixed object $I \in \mathcal{C}$.*

1. *If \mathcal{C} is complete, \mathcal{C}/I is complete.*
2. *If \mathcal{C} is cocomplete, \mathcal{C}/I is cocomplete.*

The similar result hold for coslide categories.

Notice that the identity functor $\mathbf{I}_{\mathcal{C}}$ is continuous, these results are just special cases of the following one, which we leave as exercises.

Exercises

2.24. Let \mathcal{A}, \mathcal{B} be two complete (resp. cocomplete) categories, $F: \mathcal{A} \rightarrow \mathcal{C}$ a continuous (resp. cocontinuous) functor and $G: \mathcal{B} \rightarrow \mathcal{C}$ an arbitrary functor. Show that the comma category $(F \downarrow G)$ is complete (resp. cocomplete). [Hint: use Proposition 2.3.7 and 2.3.8]

2.25. Show that the domain functor $\mathcal{C}/I \rightarrow \mathcal{C}$ and codomain functor $I/\mathcal{C} \rightarrow \mathcal{C}$ reflects limits and colimits. So the limits and colimits in slide and coslide categories are computed as limits in the original categories.

§3.3 Strong monomorphisms and epimorphisms	103
§3.4 Generators	104
§3.5 Projective and injective objects	104

§3.1 Subobjects and quotient objects

Let \mathcal{C} be a category. Naively, a **subobject** of an object X should be the isomorphism class of monomorphisms to X .

To formalize this ideal, first notice that monomorphisms to X actually form a full subcategory \mathcal{C}_X of the slice category \mathcal{C}/X . Given any two objects $(A, f), (B, g)$ in \mathcal{C}_X , since g is monic, there can not be more than one \mathcal{C} -morphisms making the following diagram commutes:

$$\begin{array}{ccc} A & \xrightarrow{\quad} & B \\ & \searrow f & \swarrow g \\ & X & \end{array}$$

Thus \mathcal{C}_X is thin. Moreover, by the triangle lemma 1.3.3, the morphisms in \mathcal{C}_X must be monic when viewed as \mathcal{C} -morphisms.

Now, we already have the category \mathcal{C}_X of monomorphisms to X . So, instead of define what are subobjects, we can just define the category of subobjects of X , denoted by $\text{Sub}_{\mathcal{C}}(X)$, as the skeleton of \mathcal{C}_X . When the category \mathcal{C} is understood, we can omit \mathcal{C} from the symbol.

Dually, a **quotient object** of an object X is just a subobject of X in the opposite category \mathcal{C}^{op} .

Remark. Notice that the notation of subobject and quotient object may not be suitable abstract of sub- and quotient in usual sense.

Example 3.1.1. In **Ring**, \mathbb{Q} is a quotient of \mathbb{Z} because the natural inclusion map $\mathbb{Z} \hookrightarrow \mathbb{Q}$ is epi (see Example 1.3.8). Similarly, In the category of monoids, \mathbb{Z} is a quotient of \mathbb{N} .

Example 3.1.2. In **Top**, the subobjects of an object are not just the subspaces. Indeed, if B has a finer topology than A , then B is also a subobject of A . The same story happened in quotient objects. In fact, for every topological space, the identity map from itself to the trivial topological space on the same underlying set is an epimorphism.

The problem is that the notions of monomorphism and epimorphism are a bit too general to capture the properties we want. So we should begin by defining some “stronger” notions.

Intersections and unions

Definition 3.1.3. If for any object x of \mathcal{C} , $\text{Sub}(X)$ is small, then we say \mathcal{C} is **well-powered**.

Since in a well-powered category, $\text{Sub}(X)$ is actually a poset, we can consider the usual order operations on it. But as we will show in later chapter, the theory of orders is just a special case of category theory, and the usual order operations can be defined in a general thin category.

Definition 3.1.4. Consider an object X of \mathcal{C} . The **intersection** of a family of subobjects is their infimum in $\text{Sub}(X)$, the **union** of a family of subobjects is their supremum.

Proposition 3.1.5. Consider an object X of a category \mathcal{C} and suppose $\text{Sub}(X)$ is a set. The following conditions are equivalent:

1. the intersection of every family of subobjects of X exists;
2. the union of every family of subobjects of X exists.

Proof. In a proset, we have

$$\begin{aligned}\sup_{i \in I} s_i &= \inf\{s \mid \forall i \in I, s_i \leq s\} \\ \inf_{i \in I} s_i &= \sup\{s \mid \forall i \in I, s \leq s_i\}\end{aligned}$$

And the results follow. \square

Remark. There is a size issue. If we do not assume that $\text{Sub}(X)$ is a set, then $\{S \mid \forall i \in I, S_i \leq S\}$ or $\{S \mid \forall i \in I, S \leq S_i\}$ may not form a set even if I is a set.

Proposition 3.1.6. The intersection of two subobjects of the same objects is given by their pullback. (see the remark of Example 2.6.12)

Proposition 3.1.7. In a complete category, the intersection of a family of subobjects of a fixed object always exists.

Proof. For a non-empty family $(s_i: S_i \rightarrow X)_{i \in I}$ of subobjects of a fixed object X , their generalized fibre product that is the limit of the diagram formed by those morphisms s_i is the intersection. For an empty intersection i.e. the terminal object, it is the identity 1_X . \square

Corollary 3.1.8. *In a complete and well-powered category, the intersection and the union of every family of subobjects of a fixed object always exist.*

Remark. At this stage one should avoid a classical mistake. Computing the union of two subobjects is by no means a problem dual to that of computing their intersection. Dualizing Proposition 3.1.6 tells us something about the poset of quotients of X , not about unions in $\text{Sub}(X)$.

In the same way let us observe that in 3.1.8 the existence of unions is by no means related to any assumption on colimits: it relies on the formal formulas used in 3.1.5. In particular a finite version of 3.1.8 does not hold: a finitely complete and well-powered category certainly admits finite intersections of subobjects (see 3.1.6), but not in general finite unions of subobjects. Finite unions have been constructed in 3.1.8 using possibly infinite intersections. For a counterexample, just consider a semilattice which is not a lattice.

Proposition 3.1.9. *In a category with (finite) coproducts and strong-epi-mono factorizations, the union of a (finite) family of subobjects always exists.*

§3.2 Factorization system

§3.3 Strong monomorphisms and epimorphisms

A monomorphism is *regular* if it behaves like an embedding. A *regular* epimorphism is a morphism $A \rightarrow B$ in a category which behaves in the way that a covering is expected to behave, in the sense that “ B is the union of the parts of A , identified with each other in some specified way”.

Definition 3.3.1. A **regular monomorphism** is a morphism which is an equaliser of some pair of parallel morphisms. A **regular epimorphism** is a coequaliser of some pair of parallel morphisms.

Example 3.3.2. The kernel of a group/ring/module/etc. homomorphism is a regular monomorphism: indeed, $\ker f$ is the equaliser of f and the zero morphism.

Example 3.3.3. In the category of topological spaces, the inclusion of a subspace $B \hookrightarrow A$ is a regular monomorphism: it is the equaliser of its characteristic map $A \rightarrow 2$ (where 2 is given the indiscrete topology) and a constant map. Conversely, every regular monomorphism is (isomorphic to) the inclusion of a subspace.

Definition 3.3.4. An **effective monomorphism** is a morphism which is the equalizer of its own cokernel pair. An **effective epimorphism** is a morphism which is the coequalizer of its own kernel pair. (ref. 2.6.6, 2.6.7)

Proposition 3.3.5. *In a finitely complete and cocomplete category, every regular monomorphism/epimorphism is effective.*

Proof. See Proposition 2.6.6. □

Definition 3.3.6. An **extremal monomorphism** is a monomorphism $f: A \rightarrow B$ that cannot be factored through a nontrivial quotient object of A . In other word, if $f = g \circ e$ with e an epimorphism, then e is an isomorphism. An **extremal epimorphism** is an epimorphism $f: A \rightarrow B$ that cannot be factored through a nontrivial subobject of B . In other word, if $f = m \circ g$ with m a monomorphism, then m is an isomorphism.

Remark. Notice that whenever we have a factorization $f = g \circ e$ of a monomorphism f , then e must be also monic. Thus if e is epi, then it is

already both monic and epi. Thus the notions of extremal monomorphism and extremal epimorphism do not make sense in a balanced category.

Proposition 3.3.7. *In a category,*

1. *every regular epimorphism is extremal,*
2. *if a composite $f \circ g$ is an extremal epimorphism, f itself is an extremal epimorphism,*
3. *a morphism which is both a monomorphism and an extremal epimorphism is an isomorphism.*

Cap.4 Universal Structures

The universal constructions in category theory include

- representable functors
- adjoint functors
- limits/colimits
- ends/coends
- Kan extensions
- dependent sums/dependent products

Each of these may be defined by requiring it to satisfy a universal property. A universal property is a property of some construction which boils down to (is manifestly equivalent to) the property that an associated object is a universal initial object of some (auxiliary) category.

In good cases, every single one of these is a special case of every other, so somehow one single concept here comes to us with many different faces.

§4.1 Adjoint functors

The key ideal of adjoint functor is that they are dual to each other.

Definition 4.1.1. Two functor $L: \mathcal{A} \rightarrow \mathcal{B}$ and $R: \mathcal{B} \rightarrow \mathcal{A}$ are said to be **adjoint**, or more explicitly L is the **left adjoint** of R and R is the **right adjoint** of L , if there exists a binary natural isomorphism

$$\mathrm{Hom}_{\mathcal{B}}(L(-), -) \cong \mathrm{Hom}_{\mathcal{A}}(-, R(-))$$

This isomorphism is called the **adjunction isomorphism** and the image of an element under this isomorphism is called its **adjunct**.

Definition 4.1.2. An **adjunction** $L \dashv R$ is a pair of two functors $L: \mathcal{A} \rightarrow \mathcal{B}$ and $R: \mathcal{B} \rightarrow \mathcal{A}$ equipped with natural transformations $\eta: \mathbf{I}_{\mathcal{A}} \rightarrow R \circ L$ (called **unit**) and $\epsilon: L \circ R \rightarrow \mathbf{I}_{\mathcal{B}}$ (called **counit**) satisfying the **triangle identities**

$$\begin{array}{ccc} L & \xrightarrow{L \circ R \circ L} & L \\ L \circ \eta \nearrow & \mathbf{I}_L & \searrow \epsilon \circ L \\ L & \xrightarrow{\quad} & L \end{array} \quad \begin{array}{ccc} R & \xrightarrow{R \circ L \circ R} & R \\ \eta \circ R \nearrow & \mathbf{I}_R & \searrow R \circ \epsilon \\ R & \xrightarrow{\quad} & R \end{array}$$

Remark. As diagrams, the triangle identities are

$$\begin{array}{c} \mathcal{A} \xrightarrow{L} \mathcal{B} \xrightarrow{R} \mathcal{A} \xrightarrow{L} \mathcal{B} \\ \begin{array}{c} \text{I}_{\mathcal{A}} \curvearrowright \downarrow \eta \\ \text{I}_{\mathcal{B}} \curvearrowleft \downarrow \epsilon \end{array} \end{array} = \mathcal{A} \xrightarrow{L} \mathcal{B}$$

and

$$\begin{array}{c} \mathcal{B} \xrightarrow{R} \mathcal{A} \xrightarrow{L} \mathcal{B} \xrightarrow{R} \mathcal{A} \\ \begin{array}{c} \text{I}_{\mathcal{A}} \curvearrowright \downarrow \eta \\ \text{I}_{\mathcal{B}} \curvearrowleft \downarrow \epsilon \end{array} \end{array} = \mathcal{B} \xrightarrow{R} \mathcal{A}$$

Proposition 4.1.3. *Two functors $L: \mathcal{A} \rightarrow \mathcal{B}$ and $R: \mathcal{B} \rightarrow \mathcal{A}$ are adjoint if and only if they form an adjunction $L \dashv R$. The left or right adjoint of any functor, if it exists, is unique up to unique isomorphism.*

Proof. If L and R are adjoint, then for any \mathcal{A} -object A , we have

$$\mathrm{Hom}_{\mathcal{B}}(L(A), L(A)) \approx \mathrm{Hom}_{\mathcal{A}}(A, R \circ L(A))$$

Thus, by taking adjuncts of identities, we get a natural transformation $\eta: \mathbf{I}_{\mathcal{A}} \rightarrow R \circ L$. Similarly, we get the other one $\epsilon: L \circ R \rightarrow \mathbf{I}_{\mathcal{B}}$.

On the other hand, by the naturality of adjunction isomorphism, we get the following commutative diagram

$$\begin{array}{ccc} \mathrm{Hom}_{\mathcal{B}}(L(A), L(A)) & \approx & \mathrm{Hom}_{\mathcal{A}}(A, R \circ L(A)) \\ \uparrow \circ (L * \eta)_{L(A)} & & \uparrow \circ \eta_A \\ \mathrm{Hom}_{\mathcal{B}}(L \circ R \circ L(A), L(A)) & \approx & \mathrm{Hom}_{\mathcal{A}}(R \circ L(A), R \circ L(A)) \end{array}$$

Thus we get

$$(\epsilon * L)_{L(A)} \circ (L * \eta)_{L(A)} = 1_{L(A)}$$

Therefore $(\epsilon * L) \circ (L * \eta) = \mathbf{I}_L$. Similarly, $(R * \epsilon) \circ (\eta * R) = \mathbf{I}_R$.

Conversely, if L and R form an adjunction, let $\eta: \mathbf{I}_{\mathcal{A}} \rightarrow R \circ L$ and $\epsilon: L \circ R \rightarrow \mathbf{I}_{\mathcal{B}}$ be the corresponding natural transformations. Then we get the following functions:

$$\begin{aligned} l_{A,B}: \mathrm{Hom}_{\mathcal{B}}(L(A), B) &\longrightarrow \mathrm{Hom}_{\mathcal{A}}(A, R(B)) \\ f &\longmapsto R(f) \circ \eta_A \end{aligned}$$

$$\begin{aligned} r_{A,B}: \mathrm{Hom}_{\mathcal{A}}(A, R(B)) &\longrightarrow \mathrm{Hom}_{\mathcal{B}}(L(A), B) \\ f &\longmapsto \epsilon_B \circ L(f) \end{aligned}$$

It is not difficult to verify that they form two mutually inverse natural transformations.

Assume L, L' are both left adjoint of R , then

$$\mathrm{Hom}_{\mathcal{B}}(L(-), -) \cong \mathrm{Hom}_{\mathcal{A}}(-, R(-)) \cong \mathrm{Hom}_{\mathcal{B}}(L'(-), -)$$

Thus, by Yoneda Lemma, $L \cong L'$. Similarly, the right adjoint is unique up to unique isomorphism. \square

Adjoint functors and representable functors

Let $F: \mathcal{A} \rightarrow \mathcal{B}$ be a functor between essentially small categories, then it induces a “pullback” functor

$$F^*: \mathbf{PSh}(\mathcal{B}) \longrightarrow \mathbf{PSh}(\mathcal{A})$$

By restriction along the Yoneda embedding $\Upsilon: \mathcal{B} \rightarrow \mathbf{PSh}(\mathcal{B})$ this yields the functor

$$\overline{F}: \mathcal{B} \xrightarrow{\Upsilon} \mathbf{PSh}(\mathcal{B}) \xrightarrow{F^*} \mathbf{PSh}(\mathcal{A})$$

Definition 4.1.4. If for some $B \in \text{ob } \mathcal{B}$, $\overline{L}(B)$ is representable and is represented by A with a universal element f , then we say (A, f) is a **coreflection** of B along F .

In plain word, (A, f) is a coreflection of B along F means

$$\phi: \text{Hom}_{\mathcal{A}}(-, A) \longrightarrow \text{Hom}_{\mathcal{B}}(F(-), B)$$

is an isomorphism and $\phi_A(1_A) = f$.

Proposition 4.1.5. F has a right adjoint if and only if every $B \in \text{ob } \mathcal{B}$ has a coreflection along F .

Proof. If F has a right adjoint R , then for any $B \in \text{ob } \mathcal{B}$, $(R(B), \epsilon_B)$ is a coreflection of it along F .

If every $B \in \text{ob } \mathcal{B}$ has a coreflection along F , then it is easy to see that the representative is functorial on \mathcal{B} , thus we get a functor $R: \mathcal{B} \rightarrow \mathcal{A}$ such that $\overline{F} \cong \Upsilon \circ R$. Then R is the right adjoint of F . \square

Similarly, we have the notion of reflection. In plain word, (A, f) is a **reflection** of B along F means

$$\phi: \text{Hom}_{\mathcal{A}}(A, -) \longrightarrow \text{Hom}_{\mathcal{B}}(B, F(-))$$

is an isomorphism and $\phi_A(1_A) = f$. Thus F has a left adjoint precisely if every $B \in \text{ob } \mathcal{B}$ has a reflection along F .

Adjoint functors and universal arrows

Definition 4.1.6. Given a functor $R: \mathcal{B} \rightarrow \mathcal{A}$, and an object A in \mathcal{A} , a **universal arrow** from A to R is an initial object of the comma category $(A \downarrow R)$. That is, it consists of an object $L(A) \in \mathcal{B}$ and a morphism $i_A: A \rightarrow R \circ L(A)$ (called the **unit**) such that for any $B \in \mathcal{B}$, any morphism $f: A \rightarrow R(B)$ factors through the unit i_A as

$$\begin{array}{ccc} & A & \\ i_A \swarrow & & \searrow f \\ R \circ L(A) & \xrightarrow{R(\tilde{f})} & R(B) \end{array}$$

for a unique $\tilde{f}: L(A) \rightarrow B$.

Proposition 4.1.7. R has a left adjoint if and only if every $A \in \text{ob } \mathcal{A}$ has a universal arrow to R .

Proof. If R has a left adjoint L . For any $A \in \text{ob } \mathcal{A}$ and $B \in \text{ob } \mathcal{B}$, let $\tilde{f}: L(A) \rightarrow B$ be the image of $f: A \rightarrow R(B)$ under the bijection

$$\text{Hom}_{\mathcal{A}}(A, R(B)) \approx \text{Hom}_{\mathcal{B}}(L(A), B)$$

and consider the naturality square

$$\begin{array}{ccc} \text{Hom}_{\mathcal{B}}(L(A), L(A)) & \approx & \text{Hom}_{\mathcal{A}}(A, R \circ L(A)) \\ \downarrow \tilde{f} \circ & & \downarrow R(\tilde{f}) \circ \\ \text{Hom}_{\mathcal{B}}(L(A), B) & \approx & \text{Hom}_{\mathcal{A}}(A, R(B)) \end{array}$$

Then the unit $i_A: A \rightarrow R \circ L(A)$ is the image of $1_{L(A)}$ under the hom-isomorphism. Chase this identity through the commuting square, we obtain

$$\begin{array}{ccc} (1_{L(A)}) & \longmapsto & (i_A) \\ \downarrow \tilde{f} \circ & & \downarrow R(\tilde{f}) \circ \\ (\tilde{f}) & \longmapsto & (f) \end{array}$$

Conversely, if every $A \in \text{ob } \mathcal{A}$ has a universal arrow $(L(A), i_A)$ to R . Then we have a bijection

$$\text{Hom}_{\mathcal{A}}(A, R(B)) \cong \text{Hom}_{\mathcal{B}}(L(A), B)$$

which it is easy to see is natural in B . In this case there is a unique way to make L into a functor so that this isomorphism is natural in A as well. \square

Adjoint functors and cographs

Recall that a graph of a function $f: X \rightarrow Y$ is the subset

$$\text{Graph}(f) = \{(x, f(x)) \mid x \in X\} \subset X \times Y$$

determined by the pullback square

$$\begin{array}{ccc} \text{Graph}(f) & \longrightarrow & Y \\ \downarrow & & \downarrow 1_Y \\ X & \xrightarrow{f} & Y \end{array}$$

Imitate this, let $F: \mathcal{A} \rightarrow \mathcal{B}$ be a functor, then the comma category $(F^{\text{op}} \downarrow \mathbf{I}_{\mathcal{B}})$ can be view as the **graph** of F . (Here we take the opposite functor for technical reason.)

On the other hand, the graph of a function can also be obtained by this square:

$$\begin{array}{ccc} \text{Graph}(f) & \longrightarrow & 1 \\ \downarrow & & \downarrow \\ X \times Y & \xrightarrow{\chi_f} & \{0, 1\} \end{array}$$

where χ_f is the characteristic function

$$\chi_f(x, y) = \begin{cases} 1 & \text{if } f(x) = y \\ 0 & \text{otherwise} \end{cases}$$

Imitate this, a graph of a functor can also be view as the category of elements of the characteristic functor χ_F

$$\chi_F: \mathcal{A}^{\text{op}} \times \mathcal{B} \xrightarrow{F^{\text{op}} \times \mathbf{I}_{\mathcal{B}}} \mathcal{B}^{\text{op}} \times \mathcal{B} \xrightarrow{\text{Hom}_{\mathcal{B}}(_, -)} \mathbf{Set}$$

Indeed, an object in $\mathbf{Elts}(\chi_F)$ is a pair $(h, \text{Hom}_{\mathcal{B}}(F^{\text{op}}(A), B))$ such that $h \in \text{Hom}_{\mathcal{B}}(F^{\text{op}}(A), B)$. It can be viewed as an object (A, h, B) in $(F^{\text{op}} \downarrow \mathbf{I}_{\mathcal{B}})$ and vice versa.

A morphism from $(h, \text{Hom}_{\mathcal{B}}(F^{\text{op}}(A), B))$ to $(h', \text{Hom}_{\mathcal{B}}(F^{\text{op}}(A'), B'))$ in $\mathbf{Elts}(\chi_F)$ is a morphism $\phi: (A, B) \rightarrow (A', B')$ in $\mathcal{A}^{\text{op}} \times \mathcal{B}$, which consists of an \mathcal{A} -morphism $f: A \rightarrow A'$ and a \mathcal{B} -morphism $g: B \rightarrow B'$, such that it induces a hom-function mapping h to h' . In other word, $g \circ h \circ F^{\text{op}}(f^{\text{op}}) = h'$.

Thus this morphism can be also viewed as a morphism from (A, h, B) to (A', h', B') .

Let's consider the notion of **cograph of a functor**, which should be dual to that of graph of a functor.

In the terminology system of Bill Lawvere, a cograph of a function $f: X \rightarrow Y$ is the quotient set determined by the pushout square

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ 1_X \downarrow & & \downarrow \\ X & \longrightarrow & \text{Cograph}(f) \end{array}$$

However, this definition is lose of fine. So Jacob Lurie give another definition in high-dimensional category theory context, see [Lur09]. Here we give the 0-dimensional case.

Let $f: X \rightarrow Y$ be a function, then it induces a functor \bar{f} from the category **2** to **Set** mapping the nonidentity arrow to f . Then the cograph of f is the category of elements of \bar{f} , as described there: the objects of $X \star^f Y$ are the disjoint union of X and Y : $\text{ob}(X \star^f Y) = X \sqcup Y$ and the nontrivial morphisms are of the form $x \rightarrow y$ whenever $x \in X, y \in Y$ and $f(x) = y$. Such a construction is obviously finer than the original one.

Imitate this, we have

Definition 4.1.8. Let $F: \mathcal{A} \rightarrow \mathcal{B}$ be a functor, the **cograph** of F is the category $\mathcal{A} \star^F \mathcal{B}$ with $\text{ob}(\mathcal{A} \star^F \mathcal{B}) = \text{ob } \mathcal{A} \sqcup \text{ob } \mathcal{B}$ and with

$$\text{Hom}_{\mathcal{A} \star^F \mathcal{B}}(A, B) = \begin{cases} \text{Hom}_{\mathcal{A}}(A, B) & \text{if } A, B \in \text{ob } \mathcal{A} \\ \text{Hom}_{\mathcal{B}}(A, B) & \text{if } A, B \in \text{ob } \mathcal{B} \\ \text{Hom}_{\mathcal{B}}(F(A), B) & \text{if } A \in \text{ob } \mathcal{A}, B \in \text{ob } \mathcal{B} \\ \emptyset & \text{if } A \in \text{ob } \mathcal{B}, B \in \text{ob } \mathcal{A} \end{cases}$$

with composition defined as induced from \mathcal{A} , from \mathcal{B} , and from the action of F .

Proposition 4.1.9. *Two functors $L: \mathcal{A} \rightarrow \mathcal{B}$ and $R: \mathcal{B} \rightarrow \mathcal{A}$ are adjoint if*

and only if $\mathcal{A} \star^L \mathcal{B}$ and $(\mathcal{B}^{\text{op}} \star^{R^{\text{op}}} \mathcal{A}^{\text{op}})^{\text{op}}$ are isomorphic under \mathcal{A} and \mathcal{B} .

$$\begin{array}{ccc} \mathcal{A} & & \mathcal{B} \\ \downarrow & \swarrow & \searrow \downarrow \\ \mathcal{A} \star^L \mathcal{B} & \approx & (\mathcal{B}^{\text{op}} \star^{R^{\text{op}}} \mathcal{A}^{\text{op}})^{\text{op}} \end{array}$$

Proof. The canonical functors from \mathcal{A} and \mathcal{B} to the cographs are the inclusions, thus an isomorphism ϕ from $\mathcal{A} \star^L \mathcal{B}$ to $(\mathcal{B}^{\text{op}} \star^{R^{\text{op}}} \mathcal{A}^{\text{op}})^{\text{op}}$ under them must work as the identity functor of \mathcal{A} and \mathcal{B} when restrict on \mathcal{A} and \mathcal{B} respectively.

Therefore, $\mathcal{A} \star^L \mathcal{B}$ and $(\mathcal{B}^{\text{op}} \star^{R^{\text{op}}} \mathcal{A}^{\text{op}})^{\text{op}}$ are isomorphic if and only if

$$\text{Hom}_{\mathcal{B}}(F(A), B) \cong \text{Hom}_{\mathcal{B}}(A, R(B))$$

naturally in $A \in \text{ob } \mathcal{A}$ and $B \in \text{ob } \mathcal{B}$. That is, L and R are adjoint. \square

Exercises

4.1. Consider the category \mathcal{C} with a single object $*$ and just two arrows: the identity 1 on $*$ and a morphism f such that $f \circ f = 1$. Show that f determines a natural transformation $\phi: \mathbf{I} \rightarrow \mathbf{I}$. The identity functor \mathbf{I} is left adjoint to itself and the unit $\eta: \mathbf{I} \rightarrow \mathbf{I} \circ \mathbf{I}$ and counit $\epsilon: \mathbf{I} \circ \mathbf{I} \rightarrow \mathbf{I}$ can both be chosen to be the identity; but they can also both be chosen to be the transformation ϕ . However, the identity and ϕ do not exhibit the adjunction.

4.2. Consider the category **Idem** whose objects are the pairs (X, v) of a set X provided with an idempotent endomorphism $v: X \rightarrow X, v \circ v = v$. A morphism $(X, v) \rightarrow (Y, w)$ is just a function $f: X \rightarrow Y$ satisfying $w \circ f = f \circ v$. There is a canonical full embedding of the category **Set** in **Idem**:

$$\begin{aligned} \iota: \mathbf{Set} &\longrightarrow \mathbf{Idem} \\ X &\longmapsto (X, 1_X) \end{aligned}$$

Consider now the functor determined by

$$\begin{aligned} j: \mathbf{Idem} &\longrightarrow \mathbf{Set} \\ (X, v) &\longmapsto \{x \in X \mid v(x) = x\} \end{aligned}$$

Prove that j is both left and right adjoint to ι .

§4.2 Properties of adjoint functors

Proposition 4.2.1. *Consider the following situation:*

$$\mathcal{A} \begin{array}{c} \xleftarrow{G} \\ \xrightarrow{F} \end{array} \mathcal{B} \begin{array}{c} \xleftarrow{K} \\ \xrightarrow{H} \end{array} \mathcal{C}$$

where F, G, H, K are functors, with G left adjoint to F and K left adjoint to H . In this case $G \circ K$ is left adjoint to $H \circ F$.

Proposition 4.2.2. *Let $L: \mathcal{A} \rightarrow \mathcal{B}$ and $R: \mathcal{B} \rightarrow \mathcal{A}$ be a pair of adjoint functors. Then L preserves colimits in \mathcal{A} , R preserves limits in \mathcal{B} .*

Proof. Let $D: \mathcal{I}^{\text{op}} \rightarrow \mathcal{B}$ be a diagram whose limit $\varprojlim D$ exists. Then we have a sequence of natural isomorphisms, natural in $A \in \text{ob } \mathcal{A}$:

$$\begin{aligned} \text{Hom}_{\mathcal{A}}(A, R(\varprojlim D)) &\cong \text{Hom}_{\mathcal{B}}(L(A), \varprojlim D) \\ &\cong \varprojlim \text{Hom}_{\mathcal{B}}(L(A), D) \\ &\cong \varprojlim \text{Hom}_{\mathcal{A}}(A, R(D)) \\ &\cong \text{Hom}_{\mathcal{A}}(A, \varprojlim R(D)) \end{aligned}$$

where we used the adjunction isomorphism and the fact that any hom-functor preserves limits (see Proposition 2.9.4). Because this is natural in A the Yoneda lemma implies that we have an isomorphism

$$R \varprojlim D \approx \varprojlim R(D)$$

The argument that shows the preservation of colimits by L is analogous. \square

Let \mathcal{I} be a small category and F a \mathcal{I} -diagram in \mathcal{C} , we have a presheaf

$$\mathcal{C} \xrightarrow{\Delta} [\mathcal{I}, \mathcal{C}] \xrightarrow{\text{Hom}(-, F)} \mathbf{Set}$$

It is not difficult to verify that it is represented by C if and only if C is a limit object of F .

Similarly, L is a colimit object of F precisely if it is a representing object of the functor

$$\mathcal{C} \xrightarrow{\Delta} [\mathcal{I}, \mathcal{C}] \xrightarrow{\text{Hom}(F, -)} \mathbf{Set}$$

Therefore, if \mathcal{C} has all \mathcal{I} -limits and colimits, we have:

Proposition 4.2.3. *Let the category \mathcal{I} be small and \mathcal{C} has all \mathcal{I} -limits and colimits. The left adjoint of the diagonal functor $\Delta: \mathcal{C} \rightarrow [\mathcal{I}, \mathcal{C}]$ sends every diagram to its colimit. The right adjoint of Δ sends every diagram to its limit.*

$$\varinjlim \dashv \Delta \dashv \varprojlim$$

Proposition 4.2.4. *Consider a functor $L: \mathcal{A} \rightarrow \mathcal{B}$ with a right adjoint $R: \mathcal{B} \rightarrow \mathcal{A}$. If \mathcal{I} is any small category, then $R_*: [\mathcal{I}, \mathcal{B}] \rightarrow [\mathcal{I}, \mathcal{A}]$ is itself right adjoint to $L_*: [\mathcal{I}, \mathcal{A}] \rightarrow [\mathcal{I}, \mathcal{B}]$.*

Proof. Let $\eta: \mathbf{I}_{\mathcal{A}} \rightarrow R \circ L$ and $\epsilon: L \circ R \rightarrow \mathbf{I}_{\mathcal{B}}$ be the natural transformations describing the adjunction $L \dashv R$. Then for any functor $F: \mathcal{I} \rightarrow \mathcal{A}$ and $G: \mathcal{I} \rightarrow \mathcal{B}$, we have corresponding natural transformations

$$\begin{aligned} \eta * G: G &\Rightarrow L_* R_* G \\ \epsilon * F: R_* L_* F &\Rightarrow F \end{aligned}$$

This yields two natural transformations

$$\begin{aligned} \bar{\eta}: \mathbf{I}_{[\mathcal{I}, \mathcal{B}]} &\Rightarrow L_* \circ R_* \\ \bar{\epsilon}: R_* \circ L_* &\Rightarrow \mathbf{I}_{[\mathcal{I}, \mathcal{A}]} \end{aligned}$$

It is easy to verify that they satisfies the triangle identities. □

Fully faithful adjoint functors

Proposition 4.2.5. *Let $L: \mathcal{A} \rightarrow \mathcal{B}$ and $R: \mathcal{B} \rightarrow \mathcal{A}$ be a pair of adjoint functors with unit $\eta: \mathbf{I}_{\mathcal{A}} \rightarrow R \circ L$ and counit $\epsilon: L \circ R \rightarrow \mathbf{I}_{\mathcal{B}}$. Then*

1. *R is faithful if and only if the counit ϵ is pointwise epi, i.e. its component over every object is an epimorphism.*
2. *L is faithful if and only if the unit η is pointwise monoic.*
3. *R is full if and only if the counit ϵ is pointwise split monoic.*
4. *L is full if and only if the unit η is pointwise split epi.*
5. *R is full and faithful if and only if the counit ϵ is a natural isomorphism.*

6. L is full and faithful if and only if the unit η is a natural isomorphism.

7. The following are equivalent:

- (a) L and R are both full and faithful;
- (b) L is an equivalence with weak inverse R ;
- (c) R is an equivalence.

Proof. For the characterization of faithful R by epi counit components, just notice that $\epsilon_X: L \circ R(X) \rightarrow X$ being an epimorphism is equivalent to the induced function

$$\text{Hom}(X, B) \rightarrow \text{Hom}(L \circ R(X), B)$$

being an injection for all objects B . By adjointness, we have an isomorphism

$$\text{Hom}(L \circ R(X), B) \approx \text{Hom}(R(X), R(B))$$

Then, by the formula for adjoints and the triangle identity, the composite of them

$$R_{X,B}: \text{Hom}(X, B) \rightarrow \text{Hom}(L \circ R(X), B) \approx \text{Hom}(R(X), R(B))$$

is computed by

$$\begin{aligned} (X \xrightarrow{f} B) &\mapsto (L \circ R(X) \longrightarrow X \xrightarrow{f} B) \\ &\mapsto (R \circ L \circ R(X) \longrightarrow R(X) \xrightarrow{R(f)} R(B)) \\ &\mapsto (R(X) \longrightarrow R \circ L \circ R(X) \longrightarrow R(X) \xrightarrow{R(f)} R(B)) \\ &= (R(X) \xrightarrow{R(f)} R(B)) \end{aligned}$$

Therefore $R_{X,B}$ is just the induced hom-function of the functor R .

The characterization of full R is just the same reasoning applied to the fact that $\epsilon_X: L \circ R(X) \rightarrow X$ is a split monomorphism iff for all objects B the induced function

$$\text{Hom}(X, B) \rightarrow \text{Hom}(L \circ R(X), B)$$

is a surjection.

The other statements can be proved analogously or just obtained as corollaries. \square

Proposition 4.2.6. *Consider a functor $F: \mathcal{A} \rightarrow \mathcal{B}$ with both a left adjoint functor G and a right adjoint functor H . If one of those adjoint functors is fully faithful, so is the other adjoint functor.*

Proof. Let $\eta: \mathbf{I}_{\mathcal{B}} \Rightarrow F \circ G$ and $\epsilon: G \circ F \Rightarrow \mathbf{I}_{\mathcal{A}}$ be the unit and counit of the adjunction $G \dashv F$, while $\alpha: \mathbf{I}_{\mathcal{A}} \Rightarrow H \circ F$ and $\beta: F \circ H \Rightarrow \mathbf{I}_{\mathcal{B}}$ be unit and counit of $F \dashv H$.

Assume G is fully faithful, then η is an isomorphism, let μ be its inverse. To show H is fully faithful, it suffices to show that β is an isomorphism.

To do this, we consider the following composite

$$\mathbf{I}_{\mathcal{B}} \xrightarrow{\eta} F \circ G \xrightarrow{F * \alpha * G} F \circ H \circ F \circ G \xrightarrow{(F \circ H) * \mu} F \circ H$$

We claim that it is the inverse of β .

First, we calculate

$$\beta \circ ((F \circ H) * \mu) \circ (F * \alpha * G) \circ \eta$$

That is the composite of the natural transformations

By the triangle identity of $F \dashv H$, the above composite becomes

Thus

$$\beta \circ ((F \circ H) * \mu) \circ (F * \alpha * G) \circ \eta = \mathbf{I}$$

Now we calculate

$$((F \circ H) * \mu) \circ (F * \alpha * G) \circ \eta \circ \beta$$

That is the composite of the natural transformations

Notice that $\mu * F = F * \epsilon$ (Since $(F * \epsilon) \circ (\eta * F) = \mathbf{I}_F$), thus the above composite becomes

By the triangle identities of $F \dashv H$ and $G \dashv F$, the above composite is just the identity transformation $\mathbf{I}_{F \circ H}$. \square

Definition 4.2.7. A pair of adjoint functors that is also an equivalence of categories is called an **adjoint equivalence**.

Corollary 4.2.8. Let $F: \mathcal{A} \rightarrow \mathcal{B}$ be an equivalence. If \mathcal{A} is (finitely) complete, then so is \mathcal{B} .

The adjoint functor theorem

Adjoint functor theorems are theorems stating that under certain conditions a functor that preserves limits is a right adjoint, and that a functor

that preserves colimits is a left adjoint. It is one of the most important result in this chapter and elementary category theory.

The basic idea of an adjoint functor theorem is that if we could assume that a category \mathcal{B} had all limits over small and large diagrams, then for $R: \mathcal{B} \rightarrow \mathcal{A}$ a functor that preserves all these limits we might define its left adjoint L by taking $L(A)$ to be the limit over the comma category $(A \downarrow R)$ of the projection functor $(A \downarrow R) \rightarrow \mathcal{B}$,

$$L(A) = \varprojlim_{A \rightarrow R(B)} B$$

Because R preserves limits, we would have an isomorphism

$$R \circ L(A) = \varprojlim_{A \rightarrow R(B)} R(B)$$

and hence an obvious morphism of cone tips $A \rightarrow R \circ L(A)$. Moreover, those morphisms form a natural transformation $\eta: \mathbf{I}_{\mathcal{A}} \rightarrow R \circ L$.

Because with this definition there would be for every B an obvious morphism (the component morphism over B of the limiting cone)

$$L \circ R(B) = \varprojlim_{R(B) \rightarrow R(B')} B' \rightarrow B$$

Moreover, those morphisms form a natural transformation $\epsilon: L \circ R \rightarrow \mathbf{I}_{\mathcal{B}}$.

It is easy to check that η and ϵ would be the unit and counit of the adjunction $L \dashv R$.

The problem with this would-be argument is that in general the comma category $(A \downarrow R)$ may not be small. But one can generally not expect a category to have all large limits: even if every $(A \downarrow R)$ is considered small, a classical theorem of Freyd says that any complete small category is a preordered set (see Proposition 2.8.2). Thus, the argument we gave above is necessarily an adjoint functor theorem for preordered sets:

Theorem 4.2.9. *If $R: \mathcal{B} \rightarrow \mathcal{A}$ is any functor between preordered sets such that \mathcal{B} has, and R preserves, all small products, then R has a left adjoint.*

To obtain adjoint functor theorems for categories that are not preordered sets, one must therefore impose various additional “size conditions” on the category \mathcal{B} and/or the functor R .

Definition 4.2.10. A functor $F: \mathcal{A} \rightarrow \mathcal{B}$ satisfies the **solution set condition** if for every \mathcal{B} -object B there exists a set S_B of \mathcal{A} -objects such that any morphism $h: B \rightarrow F(A)$ can be factored as

$$B \xrightarrow{f} F(A') \xrightarrow{F(t)} F(A)$$

for some $t: A' \rightarrow A$ and some $A' \in S_B$.

Remark. The fact that B admits a reflection (A, f) along F implies that $S_B = \{A\}$ can be chosen as solution set. So the solution set condition is a much weaker requirement than the existence of a reflection.

Theorem 4.2.11 (General adjoint functor theorem). *If a continuous functor $R: \mathcal{B} \rightarrow \mathcal{A}$ satisfies the solution set condition and \mathcal{B} is complete, then R has a left adjoint.*

Proof. Consider the full subcategory \mathcal{S}_A of $(A \downarrow R)$ whose objects are the pair (B, f) with $B \in S_A$. Since this category is small, it suffices to show that the inclusion functor $\mathcal{S}_A \hookrightarrow (A \downarrow R)$ is co-cofinal.

Indeed, the solution set condition can be reformulated as the fact that, given $(B, f) \in \text{ob}(A \downarrow R)$, there exist $(B', f') \in \text{ob} \mathcal{S}_A$ and a morphism $t: (B', f') \rightarrow (B, f)$, this is precisely the dual of requirement in Proposition 2.11.9.

Since R is continuous, $(A \downarrow R)$ is complete, and the universal arrow from A to R is just a limit over \mathcal{S}_A thus exists. \square

Theorem 4.2.12 (Special adjoint functor theorem). *A continuous functor $R: \mathcal{B} \rightarrow \mathcal{A}$ has a left adjoint, if its domain \mathcal{B} satisfies the following conditions:*

1. \mathcal{B} is complete;
2. \mathcal{B} is well-powered;
3. \mathcal{B} has a cogenerating set.

Proof. We assume that \mathcal{B} is complete, well-powered, has a cogenerating set $\{B_i\}_{i \in I}$. As before, for each object A of \mathcal{A} , the comma category $(A \downarrow R)$ is

complete. Moreover, it is easy to check that it is well-powered, and that the set of all objects of the form $A \rightarrow R(B_i)$ is a cogenerating set for $(A \downarrow R)$.

It then remains to prove that any complete, well-powered category \mathcal{C} with a cogenerating set $\{K_s\}_{s \in S}$ has an initial object. The initial object 0 is constructed as the minimal subobject of $\prod_s K_s$. Then, given $f, g: 0 \rightarrow X$, the equalizer $\ker(f, g)$ is isomorphic to 0 because 0 is minimal, and so $f = g$: there is at most one arrow $0 \rightarrow X$ for each X .

On the other hand, for each X the canonical map

$$i: X \longrightarrow \prod_{s \in S} K_s^{\text{Hom}(X, K_s)}$$

is monic since the K_s cogenerate. The following pullback of it,

$$\begin{array}{ccc} K & \longrightarrow & X \\ \downarrow & & \downarrow i \\ \prod_s K_s & \longrightarrow & \prod_s K_s^{\text{Hom}(X, K_s)} \end{array}$$

gives a subobject K of $\prod_s K_s$ that maps to X . Since 0 is minimal, there exists a morphism $0 \rightarrow K \rightarrow X$, and we conclude 0 is initial. \square

Corollary 4.2.13. *A continuous functor $R: \mathcal{B} \rightarrow \mathcal{A}$ has a left adjoint, if its domain \mathcal{B} satisfies the following conditions:*

1. \mathcal{B} is complete;
2. \mathcal{B} is well-powered;
3. \mathcal{B} has a cogenerator.

Corollary 4.2.14. *A continuous functor $R: \mathcal{B} \rightarrow \mathcal{A}$ has a left adjoint, if its domain \mathcal{B} satisfies the following conditions:*

1. \mathcal{B} is complete;
2. \mathcal{B} has a strong generating family;
3. \mathcal{B} has a cogenerating set.

Corollary 4.2.15. *A continuous functor $R: \mathcal{B} \rightarrow \mathcal{A}$ has a left adjoint, if its domain \mathcal{B} satisfies the following conditions:*

1. \mathcal{B} is complete;
2. \mathcal{B} has a strong generator;
3. \mathcal{B} has a cogenerator.

§4.3 Reflective subcategories

Definition 4.3.1. A full subcategory is **reflective** if the inclusion functor has a left adjoint. The left adjoint is sometimes called the **reflector**, and a functor which is a reflector is called a **reflection**.

Remark. Of course, there are dual notions of **coreflective subcategory**, **coreflector**, and **coreflection**.

Remark. Whenever \mathcal{A} is a full subcategory of \mathcal{B} , we can say that objects of \mathcal{A} are objects of \mathcal{B} with some extra property. But if \mathcal{A} is reflective in \mathcal{B} , then we can turn this around and (by thinking of the left adjoint as a forgetful functor) think of objects of \mathcal{B} as objects of \mathcal{A} with (if we're lucky) some extra structure or (in any case) some extra stuff.

This can always be made to work by brute force, but sometimes there is something insightful about it. For example, a metric space is a complete metric space equipped with a dense subset. Or, a possibly nonunital ring is a unital ring equipped with a unital homomorphism to the ring of integers.

Proposition 4.3.2. *Let \mathcal{A} be a reflective subcategory of \mathcal{B} . Then a morphism f is monic in \mathcal{A} if and only if it is monic in \mathcal{B} .*

Proof. The “if” is obvious. To show the “only if”, consider a monomorphism $f: A \rightarrow B$ in \mathcal{A} . Let $\iota: \mathcal{A} \hookrightarrow \mathcal{B}$ be the inclusion, r be its left adjoint and $\epsilon: r \circ \iota \rightarrow \mathbf{I}_{\mathcal{A}}$ be the counit. Then for any object T with two morphisms $x, y: T \rightarrow \iota(A)$ in \mathcal{B} , we have

$$\mathrm{Hom}_{\mathcal{B}}(T, \iota(B)) \approx \mathrm{Hom}_{\mathcal{A}}(r(T), B)$$

Then it maps $\iota(f) \circ x$ and $\iota(f) \circ y$ to $\epsilon_B \circ r(\iota(f) \circ x)$ and $\epsilon_B \circ r(\iota(f) \circ y)$. But

$$\epsilon_B \circ (r \circ \iota)(f) = f \circ \epsilon_A$$

Therefore, if $\iota(f) \circ x = \iota(f) \circ y$ then $f \circ \epsilon_A \circ r(x) = f \circ \epsilon_A \circ r(y)$, thus

$$\epsilon_A \circ r(x) = \epsilon_A \circ r(y)$$

On the other hand, we have

$$\mathrm{Hom}_{\mathcal{B}}(T, \iota(A)) \approx \mathrm{Hom}_{\mathcal{A}}(r(T), A)$$

which maps x and y to $\epsilon_A \circ r(x)$ and $\epsilon_A \circ r(y)$ respectively. Therefore, $x = y$ and thus $\iota(f)$ is monic. \square

Proposition 4.3.3. *A reflective subcategory \mathcal{A} of a (finitely) complete category \mathcal{B} is (finitely) complete.*

Proof. Let $\iota: \mathcal{A} \hookrightarrow \mathcal{B}$ be the inclusion functor with left adjoint r . For a (finitely) small diagram $D: \mathcal{I}^{\text{op}} \rightarrow \mathcal{A}$, $\iota \circ D$ is a diagram in \mathcal{B} . Since \mathcal{B} is (finitely) complete, we have a limit of $\iota \circ D$, say $\mu: \Delta_L \Rightarrow \iota \circ D$.

Consider the cone $r * \mu: \Delta_{r(L)} \Rightarrow F \circ \iota \circ D$. Since ι is fully faithful, the counit ϵ is an isomorphism, then $r \circ \iota \circ D \cong D$, thus $r * \mu$ is a cone over D . Then $\iota * r * \mu$ is a cone over $\iota \circ D$. Thus there exists a unique factorization $f: r(L) \rightarrow L$ of $\iota * r * \mu$ by μ . On the other hand, by the adjunct of $1_{r(L)}$ gives a morphism $\eta_L: L \rightarrow \iota \circ r(L)$ in \mathcal{B} .

$$\begin{array}{ccc} \iota \circ r(L) & \xrightleftharpoons[f]{\eta_L} & L \\ & \searrow_{(\iota \circ r) * \mu} & \Downarrow \mu \\ & & \iota \circ D \end{array}$$

By the naturality of the unit η , the above diagram commutes. Then $f \circ \eta_L = 1_L$. Since ι is fully faithful, we have a unique $g: r(L) \rightarrow r(L)$ such that $\iota(g) = \eta_L \circ f$. We have

$$\iota(g) \circ \eta_L = \eta_L \circ f \circ \eta_L = \eta_L = \iota(1_{r(L)}) \circ \eta_L$$

Since taking adjunct $g \mapsto \iota(g) \circ \eta_L$ is unique, $g = 1_{r(L)}$ and thus f is an isomorphism. Therefore $(\iota \circ r) * \mu$ is a limit of $\iota \circ D$ and then $r * \mu$ is a limit of D . \square

By duality, a coreflective subcategory of a cocomplete category is itself cocomplete. This obvious remark stands here just to emphasize the fact that our next result is by no means dual to the previous one.

Proposition 4.3.4. *A reflective subcategory \mathcal{A} of a (finitely) cocomplete category \mathcal{B} is (finitely) cocomplete.*

Proof. Let $\iota: \mathcal{A} \hookrightarrow \mathcal{B}$ be the inclusion functor with left adjoint r . For a (finitely) small diagram $D: \mathcal{I} \rightarrow \mathcal{A}$, $\iota \circ D$ is a diagram in \mathcal{B} . Since \mathcal{B} is

(finitely) cocomplete, we have a colimit of $\iota \circ D$, say $\mu: \iota \circ D \Rightarrow \Delta_C$. Since left adjoint preserves colimits, $r * \mu: r \circ \iota \circ D \Rightarrow \Delta_{r(C)}$ is a colimit of $r \circ \iota \circ D$. But since ι is fully faithful, the counit ϵ is an isomorphism, then $r \circ \iota \circ D \cong D$. Hence $F * \mu$ is a colimit of D . \square

Definition 4.3.5. A **localization** of a category \mathcal{B} with finite limits is a reflective subcategory \mathcal{A} of \mathcal{B} whose reflection preserves finite limits.

Definition 4.3.6. An **essential localization** of a category \mathcal{B} is a reflective subcategory \mathcal{A} of \mathcal{B} whose rejection itself admits a left adjoint.

A functor with a left adjoint preserves all limits (Proposition 4.2.2). So when \mathcal{B} has finite limits, every essential localization of \mathcal{B} is certainly a localization. Moreover if $\iota: \mathcal{A} \rightarrow \mathcal{B}$ is the canonical inclusion and $L \dashv r \dashv \iota$ are the reflection and its left adjoint, the functor L is again full and faithful (by Proposition 4.2.6). Therefore the full subcategory $L(\mathcal{A}) \subset \mathcal{B}$ is, up to an equivalence, a coreflective subcategory of \mathcal{B} . It should be noticed that L has in general no reason at all to coincide with the canonical inclusion ι .

Proposition 4.3.7. *Consider a category \mathcal{B} with finite limits and filtered colimits, and a localization \mathcal{A} of \mathcal{B} . If in \mathcal{B} , finite limits commute with filtered colimits, the same property holds in \mathcal{A} .*

Proof. Let $\iota: \mathcal{A} \rightarrow \mathcal{B}$ be the canonical inclusion and r be its left adjoint. Consider a diagram

$$D: \mathcal{I} \times \mathcal{J} \longrightarrow \mathcal{A}$$

with \mathcal{I} finite and \mathcal{J} filtered.

The proof of Proposition 4.3.3 shows that

$$\varinjlim_{\mathcal{J}} D \approx r(\varinjlim_{\mathcal{J}} \iota \circ D)$$

Then, by proof of Proposition 4.3.4,

$$\varinjlim_{\mathcal{I}} r(\varinjlim_{\mathcal{J}} \iota \circ D) \approx r(\varinjlim_{\mathcal{I}} \iota \circ r(\varinjlim_{\mathcal{J}} \iota \circ D))$$

Notice that ι, r preserve limits and r preserves colimits, we have

$$r(\varinjlim_{\mathcal{I}} \iota \circ r(\varinjlim_{\mathcal{J}} \iota \circ D)) \approx r \circ \iota \circ r(\varinjlim_{\mathcal{I}} \varinjlim_{\mathcal{J}} \iota \circ D)$$

Since finite limits commute with filtered colimits in \mathcal{B} , we have

$$\varinjlim_{\mathcal{I}} \varprojlim_{\mathcal{J}} \iota \circ D \approx \varprojlim_{\mathcal{J}} \varinjlim_{\mathcal{I}} \iota \circ D$$

Based on the above, we have

$$\begin{aligned} \varinjlim_{\mathcal{I}} \varprojlim_{\mathcal{J}} D &\approx r \circ \iota \circ r(\varprojlim_{\mathcal{J}} \varinjlim_{\mathcal{I}} \iota \circ D) \\ &\approx r \circ \iota(\varprojlim_{\mathcal{J}} \varinjlim_{\mathcal{I}} r \circ \iota \circ D) \\ &\approx \varprojlim_{\mathcal{J}} \varinjlim_{\mathcal{I}} D \end{aligned}$$

Where the last isomorphism is based on the constructions in proof of Proposition 4.3.3 and 4.3.4. \square

Epireflective subcategories

Definition 4.3.8. Consider a category \mathcal{B} and a reflective subcategory \mathcal{A} of \mathcal{B} . Its reflection r is said to be an **epireflection** if the unit $\eta: \mathbf{I}_{\mathcal{B}} \rightarrow \iota \circ r$ is pointwise epi.

Proposition 4.3.9. Consider a category \mathcal{B} in which every morphism can be factored as an epimorphism followed by a strong monomorphism. For a reflective subcategory $r \dashv \iota: \mathcal{A} \hookrightarrow \mathcal{B}$, the following conditions are equivalent:

1. the reflection is an epireflection;
2. given a strong monomorphism $u: B \rightarrow \iota(A)$ in \mathcal{B} , then the object B belongs to \mathcal{A} ,

§4.4 Kan extensions

The **Kan extension** of a functor $F: \mathcal{A} \rightarrow \mathcal{B}$ with respect to a functor $p: \mathcal{A} \rightarrow \mathcal{A}'$ is, if it exists, a kind of best approximation to the problem of finding a functor $\mathcal{A}' \rightarrow \mathcal{B}$ such that

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{F} & \mathcal{B} \\ p \downarrow & \nearrow & \\ \mathcal{A}' & & \end{array}$$

hence to extending the domain of F through p from \mathcal{A} to \mathcal{A}' .

Similarly, a **Kan lift** is the best approximation to lifting a functor $F: \mathcal{A} \rightarrow \mathcal{B}$ through a functor $q: \mathcal{B}' \rightarrow \mathcal{B}$ to a functor $\hat{F}: \mathcal{A} \rightarrow \mathcal{B}'$:

$$\begin{array}{ccc} & \mathcal{B}' & \\ \hat{F} \nearrow & & \downarrow q \\ \mathcal{A} & \xrightarrow{F} & \mathcal{B} \end{array}$$

Kan extensions are ubiquitous.

Definition 4.4.1. Consider two functors $F: \mathcal{A} \rightarrow \mathcal{B}$ and $p: \mathcal{A} \rightarrow \mathcal{A}'$. The **left Kan extension** of F along p , if it exists, is a pair (G, α) where

- $G: \mathcal{A}' \rightarrow \mathcal{B}$ is a functor;
- $\alpha: F \Rightarrow G \circ p$ is a natural transformation

satisfying the following universal property: if (H, β) is another pair with

- $H: \mathcal{A}' \rightarrow \mathcal{B}$ is a functor;
- $\beta: F \Rightarrow H \circ p$ is a natural transformation

there exists a unique natural transformation $\gamma: G \Rightarrow H$ satisfying the equality $(\gamma * p) \circ \alpha = \beta$.

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{F} & \mathcal{B} \\ p \searrow & \Downarrow \alpha & \nearrow G \\ & \mathcal{A}' & \end{array} \quad \begin{array}{c} \nearrow H \\ \Downarrow \gamma \end{array}$$

We shall use the notation $\text{Lan}_p F$ to denote the **left Kan extension** of F along p . The notation $\text{Ran}_p F$ is used for the dual notion of **right Kan extension**.

Let $p: \mathcal{A} \rightarrow \mathcal{A}'$ be a functor between small categories. For \mathcal{B} any other category, write

$$p^*: [\mathcal{A}', \mathcal{B}] \rightarrow [\mathcal{A}, \mathcal{B}]$$

for the induced functor which sends a functor $H: \mathcal{A}' \rightarrow \mathcal{B}$ to the composite functor $H \circ p: \mathcal{A} \rightarrow \mathcal{A}' \rightarrow \mathcal{B}$.

Then the left Kan extension of F along p is precisely a corepresentation of the functor $\text{Hom}_{[\mathcal{A}, \mathcal{B}]}(F, p^*(-))$, which is a specified natural isomorphism

$$\text{Hom}_{[\mathcal{A}, \mathcal{B}]}(F, p^*(-)) \cong \text{Hom}_{[\mathcal{A}', \mathcal{B}]}(\text{Lan}_p F, -)$$

with corepresenting object $\text{Lan}_p F$.

Moreover, if for any functor $F: \mathcal{A} \rightarrow \mathcal{B}$, its left Kan extension along p exists, then those corepresenting objects form a functor

$$\text{Lan}_p: [\mathcal{A}, \mathcal{B}] \rightarrow [\mathcal{A}', \mathcal{B}]$$

left adjoint to p^* .

Definition 4.4.2. Let $p: \mathcal{A} \rightarrow \mathcal{A}'$ be a functor and p^* its induced pullback functor. The left adjoint of p^* , if it exists, is called the **left Kan extension operation** along p and denoted by $p_!$ or Lan_p . The right adjoint, if it exists, is called the **right Kan extension operation** along p and denoted by p_* or Ran_p .

Use the fact that $[\mathbf{1}, \mathcal{A}] \simeq \mathcal{A}$ and Proposition 4.2.3, we have

Proposition 4.4.3. *Let \mathcal{A}' be the terminal category $\mathbf{1}$, then*

1. *the left Kan extension operation forms the colimit of a functor;*
2. *the right Kan extension operation forms the limit of a functor.*

Preserving Kan extensions

Definition 4.4.4. We say that a Kan extension $\text{Lan}_p F$ is **preserved** by a functor G if the composite $G \circ \text{Lan}_p F$ is a Kan extension of $G \circ F$ along p , and moreover the universal natural transformation $G \circ F \Rightarrow G \circ \text{Lan}_p F \circ p$ is the composite of G with the universal transformation $F \Rightarrow \text{Lan}_p F \circ p$.

Proposition 4.4.5. *Left adjoint functor preserves left Kan extensions.*

Proof. Let L be a functor with right adjoint R , then we need to show that $L \circ \text{Lan}_p F = \text{Lan}_p(L \circ F)$.

$$\begin{array}{ccccc} \mathcal{A} & \xrightarrow{F} & \mathcal{B} & \xrightleftharpoons[L]{L} & \mathcal{C} \\ p \downarrow & \nearrow \text{Lan}_p F & & \nearrow R & \\ \mathcal{A}' & \xrightarrow{\text{Lan}_p(L \circ F)} & & & \end{array}$$

Indeed, for any functor $G: \mathcal{A}' \rightarrow \mathcal{C}$, we have

$$\begin{aligned} \text{Nat}(L \circ \text{Lan}_p F, G) &\approx \text{Nat}(\text{Lan}_p F, R \circ G) \\ &\approx \text{Nat}(F, R \circ G \circ p) \\ &\approx \text{Nat}(L \circ F, G \circ p) \\ &\approx \text{Nat}(\text{Lan}_p(L \circ F), G) \end{aligned}$$

So $L \circ \text{Lan}_p F = \text{Lan}_p(L \circ F)$, by putting successively $H = L \circ \text{Lan}_p F$ and $H = \text{Lan}_p(L \circ F)$. \square

Proposition 4.4.6. *Consider a functor $p: \mathcal{A} \rightarrow \mathcal{A}'$ between small categories. The following conditions are equivalent:*

1. p has a right adjoint q ;
2. $\text{Lan}_p \mathbf{I}_{\mathcal{A}}$ exists, and for every functor $F: \mathcal{A} \rightarrow \mathcal{B}$, the isomorphism $F \circ \text{Lan}_p \mathbf{I}_{\mathcal{A}} \cong \text{Lan}_p F$ holds;
3. $\text{Lan}_p \mathbf{I}_{\mathcal{A}}$ exists, and the isomorphism $p \circ \text{Lan}_p \mathbf{I}_{\mathcal{A}} \cong \text{Lan}_p p$ holds.

$$\begin{array}{ccccc} \mathcal{A} & \xrightarrow{\mathbf{I}_{\mathcal{A}}} & \mathcal{A} & \xrightarrow{F} & \mathcal{B} \\ p \downarrow & \nearrow \text{Lan}_p \mathbf{I}_{\mathcal{A}} & & \nearrow \text{Lan}_p F & \\ \mathcal{A}' & \xrightarrow{\text{Lan}_p p} & & & \end{array}$$

Proof. For $1 \Rightarrow 2$, let $\eta: \mathbf{I}_{\mathcal{A}} \Rightarrow q \circ p$ and $\epsilon: p \circ q \Rightarrow \mathbf{I}_{\mathcal{A}'}$ be the unit and counit of the adjunction $p \dashv q$, then we get a natural transformation $\alpha = F * \eta$. For any functor $G: \mathcal{A}' \rightarrow \mathcal{B}$ and natural transformation $\beta: F \Rightarrow G \circ p$, consider

the composite

$$\begin{array}{ccccc}
 & & F & & \\
 & \nearrow & \Downarrow \beta & \searrow & \\
 \mathcal{A}' & \xrightarrow{q} & \mathcal{A} & \xrightarrow{p} & \mathcal{A}' & \xrightarrow{G} & \mathcal{B} \\
 & \searrow & \Downarrow \epsilon & \nearrow & & \\
 & & \mathbf{I}_{\mathcal{A}'} & &
 \end{array}$$

$$\gamma = (G * \epsilon) \circ (\beta * q): F \circ q \Rightarrow G \circ p \circ q \Rightarrow G$$

Then, by the triangle identity, it is not difficult to see that $(\gamma * p) \circ \alpha = \beta$ from the following calculation

$$\begin{array}{ccccccc}
 & & \mathbf{I}_{\mathcal{A}} & & F & & F \\
 & \nearrow & \Downarrow \eta & \searrow & \Downarrow \beta & \searrow & \Downarrow \beta \\
 \mathcal{A} & \xrightarrow{p} & \mathcal{A}' & \xrightarrow{q} & \mathcal{A} & \xrightarrow{p} & \mathcal{A}' & \xrightarrow{G} & \mathcal{B} \\
 & & \Downarrow \epsilon & & & & & & \\
 & & \mathbf{I}_{\mathcal{A}'} & & & & & &
 \end{array} = \begin{array}{ccc}
 & F & \\
 & \Downarrow \beta & \\
 \mathcal{A} & \xrightarrow{p} & \mathcal{A}' & \xrightarrow{G} & \mathcal{B}
 \end{array}$$

To see such γ is unique, consider another natural transformation γ' such that $(\gamma' * p) \circ \alpha = \beta$, i.e.

$$\begin{array}{ccccccc}
 & & \mathbf{I}_{\mathcal{A}} & & F & & \\
 & \nearrow & \Downarrow \eta & \searrow & \Downarrow \beta & \searrow & \\
 \mathcal{A} & \xrightarrow{p} & \mathcal{A}' & \xrightarrow{q} & \mathcal{A} & \xrightarrow{F} & \mathcal{B} \\
 & & \Downarrow \gamma' & & & & \\
 & & G & & & &
 \end{array} = \begin{array}{ccc}
 & F & \\
 & \Downarrow \beta & \\
 \mathcal{A} & \xrightarrow{p} & \mathcal{A}' & \xrightarrow{G} & \mathcal{B}
 \end{array}$$

Therefore, we have

$$\begin{aligned}
\mathcal{A}' \xrightarrow{q} \mathcal{A} \xrightarrow{F} \mathcal{B} &= \mathcal{A}' \xrightarrow{q} \mathcal{A} \xrightarrow{p} \mathcal{A}' \xrightarrow{q} \mathcal{A} \xrightarrow{F} \mathcal{B} \\
&\quad \Downarrow \gamma' \quad \Downarrow \epsilon \quad \Downarrow \eta \quad \Downarrow \gamma' \\
&\quad G \quad \mathbf{I}_{\mathcal{A}'} \quad \mathbf{I}_{\mathcal{A}} \quad G
\end{aligned}$$

$$\begin{aligned}
&= \mathcal{A}' \xrightarrow{q} \mathcal{A} \xrightarrow{p} \mathcal{A}' \xrightarrow{G} \mathcal{B} \\
&\quad \Downarrow \epsilon \quad \Downarrow \beta \quad F \\
&\quad \mathbf{I}_{\mathcal{A}'}
\end{aligned}$$

$$\begin{aligned}
\gamma' &= \gamma' \circ (F * q * \epsilon) \circ (\alpha * q) \\
&= (G * \epsilon) \circ (\gamma' * p * q) \circ (\alpha * q) \\
&= (G * \epsilon) \circ (\beta * q) = \gamma
\end{aligned}$$

This prove $\text{Lan}_p F = F \circ q$ for every functor $F: \mathcal{A} \rightarrow \mathcal{B}$. Specially, $\text{Lan}_p \mathbf{I}_{\mathcal{A}} = q$.

$2 \Rightarrow 3$ is obvious.

For $3 \Rightarrow 1$, we need to show that $\text{Lan}_p \mathbf{I}_{\mathcal{A}}$ is the right adjoint of p . The canonical natural transformation $\eta: \mathbf{I}_{\mathcal{A}} \Rightarrow (\text{Lan}_p \mathbf{I}_{\mathcal{A}}) \circ p$ should be the unit. It suffices to construct the counit and check the triangle identities.

Set $q = \text{Lan}_p \mathbf{I}_{\mathcal{A}}$. By our assumption, $\alpha = p * \eta: p \Rightarrow p \circ q \circ p$ is the canonical natural transformation of $\text{Lan}_p p$.

Consider the functor $\mathbf{I}_{\mathcal{A}'}: \mathcal{A}' \rightarrow \mathcal{A}'$ and the natural transformation $\mathbf{I}_p: p \Rightarrow p$. Then, by the universal property of Kan extension. there exists a unique natural transformation $\epsilon: p \circ q \Rightarrow \mathbf{I}_{\mathcal{A}'}$ such that $(\epsilon * p) \circ \alpha = \mathbf{I}_p$,

which is just the triangle identity

$$\begin{array}{c}
 \mathcal{A} \xrightarrow{p} \mathcal{A}' \xrightarrow{q} \mathcal{A} \xrightarrow{p} \mathcal{A}' = \mathcal{A} \xrightarrow{p} \mathcal{A}' \\
 \begin{array}{ccc}
 \text{I}_{\mathcal{A}} & \Downarrow \eta & \\
 & \text{I}_{\mathcal{A}'} & \\
 & \Downarrow \epsilon &
 \end{array}
 \end{array}$$

For the other triangle identity, consider that the composite $(q*\epsilon) \circ (\eta*q)$ satisfying

$$\begin{array}{c}
 \mathcal{A} \xrightarrow{p} \mathcal{A}' \xrightarrow{q} \mathcal{A} \xrightarrow{p} \mathcal{A}' \xrightarrow{q} \mathcal{A} = \mathcal{A} \xrightarrow{p} \mathcal{A}' \xrightarrow{q} \mathcal{A} \\
 \begin{array}{ccccc}
 \text{I}_{\mathcal{A}} & \Downarrow \eta & \text{I}_{\mathcal{A}} & \Downarrow \eta & \text{I}_{\mathcal{A}} \\
 & \text{I}_{\mathcal{A}'} & & \text{I}_{\mathcal{A}'} &
 \end{array}
 \end{array}$$

For functor $q: \mathcal{A}' \rightarrow \mathcal{A}$ and natural transformation $\eta: \mathbf{I}_{\mathcal{A}} \Rightarrow q \circ p$, the factorization $\gamma: q \Rightarrow q$ satisfying $(\gamma * p) \circ \eta = \eta$ is unique. Therefore, $(q * \epsilon) \circ (\eta * q) = \mathbf{I}_q$ and thus η, ϵ are the unit and counit of adjunction $p \dashv q$. \square

Remark. This proposition also shows that adjoint functions are special Kan extensions.

Pointwise Kan extension

Theorem 4.4.7. *Let $F: \mathcal{A} \rightarrow \mathcal{B}$ be a functor from a small category \mathcal{A} to a cocomplete category \mathcal{B} . Then for any $p: \mathcal{A} \rightarrow \mathcal{A}'$, the left Kan extension of F along p exists and its value on an object X in \mathcal{A}' is given by the colimit*

$$(\text{Lan}_p F)(X) \cong \varinjlim ((p \downarrow \Delta_X) \rightarrow \mathcal{A} \xrightarrow{F} \mathcal{B})$$

where

- $(p \downarrow \Delta_X)$ is the comma category;
- $(p \downarrow \Delta_X) \rightarrow \mathcal{A}$ is the domain functor.

Likewise, if \mathcal{B} is complete, then for any $p: \mathcal{A} \rightarrow \mathcal{A}'$, the right Kan extension of F along p exists and its value on an object X in \mathcal{A}' is given by the limit

$$(\text{Ran}_p F)(X) \cong \varprojlim ((\Delta_X \downarrow p) \rightarrow \mathcal{A} \xrightarrow{F} \mathcal{B})$$

where

- $(\Delta_X \downarrow p)$ is the comma category;
- $(\Delta_X \downarrow p) \rightarrow \mathcal{A}$ is the codomain functor.

Proof. Consider the case of the left Kan extension, the other case works analogously, but dually.

First notice that the above pointwise definition of values of a functor canonically extends to an actual functor:

For any morphism $f: X_1 \rightarrow X_2$ in \mathcal{A}' , we get a functor

$$(p \downarrow \Delta_{X_1}) \longrightarrow (p \downarrow \Delta_{X_2})$$

of comma categories, by postcomposition. Then we get a morphism from the diagram

$$(p \downarrow \Delta_{X_1}) \rightarrow \mathcal{A} \xrightarrow{F} \mathcal{B}$$

to

$$(p \downarrow \Delta_{X_2}) \rightarrow \mathcal{A} \xrightarrow{F} \mathcal{B}$$

which induces canonically a corresponding morphism of their colimits.

$$(\text{Lan}_p F)(X_1) \longrightarrow (\text{Lan}_p F)(X_2)$$

Now we consider that, for any X in \mathcal{A}' , as a cocone of the diagram

$$(p \downarrow \Delta_X) \rightarrow \mathcal{A} \xrightarrow{F} \mathcal{B}$$

$(\text{Lan}_p F)(X)$ gives a family of commutative diagrams:

$$\begin{array}{ccccc}
 (p \downarrow \Delta_X) & (p(A_1) \xrightarrow{f} X) & \xrightarrow{p(h)} & (p(A_2) \xrightarrow{g} X) & \\
 \mathcal{B} & F(A_1) & \xrightarrow{F(h)} & F(A_2) & \\
 & \searrow s_f & & \swarrow s_g & \\
 & & (\text{Lan}_p F)(X) & &
 \end{array}$$

and induces a natural transformation

$$\eta_F: F \Rightarrow p^* \text{Lan}_p F$$

satisfying the required universal property by taking

$$\eta_F(A) = s_{1_{p(A)}}: F(A) \rightarrow (\text{Lan}_p F)(p(A)).$$

It is straightforward, if somewhat tedious, to check that these are natural, and that the natural transformation defined this way has the required universal property. \square

A Kan extension is called pointwise when every $\text{Lan}_p F(X)$ can be computed by the colimit formula in this theorem. It should be noted, though, that pointwise Kan extensions can still exist, and hence the particular requisite (co)limits exist, even if \mathcal{B} is not (co)complete.

Here, we give a formal definition of pointwise Kan extension that doesn't rely on any computational framework

Definition 4.4.8. A right Kan extension is called **pointwise** when it is p -reserved by all representable functors. A left Kan extension is called **pointwise** when its opposite is a pointwise right Kan extension.

Theorem 4.4.9. A right Kan extension $\text{Ran}_p F$ is pointwise if and only if for any X in \mathcal{A}' , the limit $\varprojlim((\Delta_X \downarrow p) \rightarrow \mathcal{A} \xrightarrow{F} \mathcal{B})$ exists. Dually, a left Kan extension $\text{Lan}_p F$ is pointwise if and only if for any X in \mathcal{A}' , the colimit $\varinjlim((p \downarrow \Delta_X) \rightarrow \mathcal{A} \xrightarrow{F} \mathcal{B})$ exists.

Proof. Since representable functors preserve limits, the “if” is obvious.

Conversely, assume the right Kan extension $\text{Ran}_p F$ is pointwise. Then for any X in \mathcal{A}' , we need to show that $(\text{Ran}_p F)(X)$ is the limit of the composite $(\Delta_X \downarrow p) \rightarrow \mathcal{A} \xrightarrow{F} \mathcal{B}$.

Let H denote the composite of the representable functor $\text{Hom}_{\mathcal{B}}(B, -)$ with $\text{Ran}_p F$. Then by the covariant Yoneda lemma,

$$\text{Nat}(\text{Hom}_{\mathcal{A}'}(X, -), H) \approx H(X)$$

By our assumption, H is the right Kan extension of the composite of $\text{Hom}_{\mathcal{B}}(B, -)$ and F , so we have

$$\text{Hom}_{[\mathcal{A}, \text{Set}]}(p^*(-), \text{Hom}_{\mathcal{B}}(B, F(-))) \cong \text{Hom}_{[\mathcal{A}', \text{Set}]}(-, H)$$

Therefore we get the following bijection.

$$\mathrm{Hom}_{\mathcal{B}}(B, (\mathrm{Ran}_p F)(X)) \approx \mathrm{Nat}(\mathrm{Hom}_{\mathcal{A}'}(X, p(-)), \mathrm{Hom}_{\mathcal{B}}(B, F(-)))$$

It is not difficult to see that the right side set is equivalent to the set of cones over the composite $(\Delta_X \downarrow p) \rightarrow \mathcal{A} \xrightarrow{F} \mathcal{B}$. Thus $(\mathrm{Ran}_p F)(X)$ is its limit. \square

Proposition 4.4.10. *Let $\mathrm{Lan}_p F$ be a pointwise Kan extension with p fully faithful, then the canonical natural transformation $\eta_F: F \Rightarrow p^*(\mathrm{Lan}_p F)$ is an isomorphism.*

Proof. In the proof of Theorem 4.4.9, we have constructed the natural transformation

$$\eta_F: F \Rightarrow p^*(\mathrm{Lan}_p F)$$

whose component $\eta_F(A)$ at $A \in \mathrm{ob} \mathcal{A}$ is the component $s_{1_{p(A)}}$ of the colimit cocone

$$\varinjlim((p \downarrow \Delta_X) \rightarrow \mathcal{A} \xrightarrow{F} \mathcal{B})$$

under index $(A, 1_{p(A)})$.

Therefore, to show η_F is an isomorphism, it suffices to show that for every $A \in \mathrm{ob} \mathcal{A}$, $s_{1_{p(A)}}$ is an isomorphism. To do this, we shall point out that $(A, 1_{p(A)})$ is a terminal object in $(p \downarrow \Delta_{p(A)})$, then the colimit is just $F(A)$ and $s_{1_{p(A)}} = 1_{F(A)}$.

Indeed, for any (A', g) in $(p \downarrow \Delta_{p(A)})$, since p is fully faithful, there exists a unique morphism $f \in \mathrm{Hom}(A', A)$ such that $p(f) = g$. Then f is a morphism from (A', g) to $(A, 1_{p(A)})$. Conversely, for any morphism f from (A', g) to $(A, 1_{p(A)})$, we have $p(f) = g$. Thus $(A, 1_{p(A)})$ is the terminal object. \square

Exercises

4.3. Consider two functors $p: \mathcal{A} \rightarrow \mathcal{A}'$ and $F: \mathcal{A} \rightarrow \mathcal{B}$, with the property

$$\forall A, A' \in \mathrm{ob} \mathcal{A}, \forall f, f': A \rightarrow A', F(f) = F(f') \implies p(f) = p(f')$$

Suppose $\mathcal{A}, \mathcal{A}'$ are small, \mathcal{B} is cocomplete and p is full. Show that $\mathrm{Lan}_p F$ exists and the isomorphism $F = \mathrm{Lan}_p F \circ p$ holds.

4.4. Consider a functor $p: \mathcal{A} \rightarrow \mathcal{A}'$ between small categories. For each object A in \mathcal{A} , the Kan extension $\text{Lan}_p \text{Hom}_{\mathcal{A}}(A, -)$ exists and is given by $\text{Hom}_{\mathcal{A}'}(p(A), -)$. [Hint: apply the Yoneda lemma.] The equality

$$\text{Lan}_p \text{Hom}_{\mathcal{A}}(A, -) \circ p = \text{Hom}_{\mathcal{A}}(A, -)$$

holds precisely when p is fully faithful.

4.5. Consider the category $\mathbf{1}$ with a single object A and a single arrow 1_A , the category $\mathbf{2}$ with two distinct objects A, B and just the identity arrows $1_A, 1_B$, and the category $\vec{\mathbf{2}}$ with two distinct objects A, B , the identity arrows $1_A, 1_B$ and an additional arrow $f: B \rightarrow A$. Define the functors $p: \mathbf{1} \rightarrow \vec{\mathbf{2}}$ and $F: \mathbf{1} \rightarrow \mathbf{2}$ by $p(A) = A, F(A) = A$. Observe that the only two functors from $\vec{\mathbf{2}}$ to $\mathbf{2}$ are the constant functors Δ_A and $\Delta_{A'}$. Check that A is the left Kan extension $\text{Lan}_p F$. Prove that $(p \downarrow \Delta_A)$ is an empty category and $\Delta_A(B)$ is not isomorphic to the colimit of $(p \downarrow \Delta_X) \rightarrow \mathbf{1} \xrightarrow{F} \mathbf{2}$. So the Kan extension $\text{Lan}_p F$ is not pointwise.

Cap.5 Order Theory

In this chapter, we introduce some basic concepts in order theory by treat it as a special case of category theory.

§5.1 Relations and orders

Definition 5.1.1. Given a family $(S_i)_{i \in I}$ of sets, a **relation** on that family is a subset R of the cartesian product $\prod_{i \in I} S_i$.

A **unary relation** on A is a relation on the singleton family (A) . This is the same as a subset of A .

A **binary relation** on A and B is a relation on the family (A, B) , that is a subset of $A \times B$. This is also called a relation from A to B .

A **binary relation** on A is a relation on (A, A) , that is a relation from A to itself. This is sometimes called simply a relation on A .

An n -**ary relation** on A is a relation on a family of n copies of A , that is a subset of A^n .

For a binary relation, one often uses a symbol such as \sim and writes $a \sim b$ instead of $(a, b) \in \sim$. Actually, even when a relation is given by a letter such as R , one often sees aRb instead of $(a, b) \in R$, although now that does not look so good.

Binary relations form a 2-category **Rel**.

The objects are sets, the morphisms from A to B are the binary relations from A to B , and there is a 2-morphism from R to S (both from A to B) if R implies S (that is, when $(a, b) \in R$, then $(a, b) \in S$).

The interesting definition is composition

Definition 5.1.2. If R is a relation from A to B and S is a relation from B to C , then their **composite relation** $S \circ R$ from A to C is defined as follows:

$$(a, c) \in S \circ R \iff \exists b \in B, (a, b) \in R \wedge (b, c) \in S$$

The identity morphism is given by **equality** (also called **diagonal**):

$$1_A = \Delta_A := \{(a, a) \mid a \in A\}$$

Moreover, there exists another operation on **Rel**, the **reverse**:

$$R^{\text{op}} := \{(y, x) \mid (x, y) \in R\}$$

It is obvious that:

$$(S \circ R)^{\text{op}} = R^{\text{op}} \circ S^{\text{op}} \quad 1_A^{\text{op}} = 1_A$$

Definition 5.1.3. A binary relation \sim on a set A is **transitive** if in every chain of three pairwise related elements $x \sim y, y \sim z$, the first and last elements are also related $x \sim z$.

In **Rel**, a relation $R: A \rightarrow A$ is transitive if and only if it contains its composite with itself:

$$R^2 \subset R$$

from which it follows that $R^n \subset R$ for any natural number n except $n = 0$.

Definition 5.1.4. A binary relation \sim on a set A is **reflexive** if every element of A is related to itself.

In **Rel**, a relation $R: A \rightarrow A$ is reflexive if and only if it contains the equality:

$$1_A \subset R$$

The antithetical case is

Definition 5.1.5. A binary relation \sim on a set A is **irreflexive** if no element of A is related to itself.

In **Rel**, a relation $R: A \rightarrow A$ is irreflexive if and only if it is disjoint from the equality:

$$1_A \cap R = \emptyset$$

Another interesting case is

Definition 5.1.6. A binary relation \sim on a set A is **symmetric** if any two elements that are related in one order are also related in the other order.

In **Rel**, a relation $R: A \rightarrow A$ is symmetric if and only if it contains its reverse:

$$R^{\text{op}} \subset R$$

Definition 5.1.7. A binary relation \sim on a set A is **antisymmetric** if any two elements that are related in both orders are equal.

In **Rel**, a relation $R: A \rightarrow A$ is antisymmetric if and only if its intersection with its reverse is contained in the equality:

$$R^{\text{op}} \cap R \subset 1_A$$

Definition 5.1.8. A binary relation \sim on a set A is **asymmetric** if no two elements are related in both orders.

In **Rel**, a relation $R: A \rightarrow A$ is asymmetric if and only if it is disjoint from its reverse:

$$R^{\text{op}} \cap R = \emptyset$$

The next important case is

Definition 5.1.9. A binary relation \sim on a set A is **total** if any two elements that are related in one order or the other.

In **Rel**, a relation $R: A \rightarrow A$ is total if and only if its union with its reverse is the **universal relation**:

$$R^{\text{op}} \cup R = A \times A$$

Definition 5.1.10. A binary relation \sim on an set A is **left euclidean** if every two elements both related to a third are also related to each other. A relation \sim is **right euclidean** if this works in the other order.

Remark. One could also say **euclidean** and **coeuclidean** or **opeuclidean**.

In **Rel**, a relation $R: A \rightarrow A$ is left euclidean if and only if it contains its composite with its reverse:

$$R^{\text{op}} \circ R \subset R$$

a relation $R: A \rightarrow A$ is right euclidean if and only if it contains the composite of its reverse with itself:

$$R \circ R^{\text{op}} \subset R$$

An important example of the combination of those concepts is

Definition 5.1.11. An **equivalence relation** on a set S is a binary relation \sim on S that is reflexive, symmetric and transitive.

Proposition 5.1.12. *A binary relation is an equivalence relation if and only if it is reflexive and euclidean in either direction.*

Orders

An **order** on a set S is a binary relation that is, at least, transitive.

Actually, there are several different notions of order that are each useful in their own ways:

- A **preorder** on a set S is a reflexive and transitive relation, generally written \leq . A **preordered set**, or **proset**, is a set equipped with a preorder.
- A **quasiorder** (or **strict preorder**) on a set S is a irreflexive and transitive relation, generally written $<$. A **quasiordered set**, or **quoset**, is a set equipped with a quasiorder.
- A **partial order** on a set S is an antisymmetric preorder. A **partial ordered set**, or **poset**, is a set equipped with a partial order.
- A **total order** on a set S is a total partial order. A **total ordered set**, or **toset**, is a set equipped with a total order.

For a preorder \leq , one can define its strict preorder $<$ by subtracting the diagonal. Conversely, a preorder can be obtained by putting $x \leq y$ whenever $x < y$ or $x = y$.

We have already seen that a poset can be viewed as a category (see Example 1.2.2). Then all posets form a 2-category, called **Pos**.

A morphism $f: A \rightarrow B$ between two poset (A, \leq) and (B, \leq) is a functor by definition. In other word, f is a function preserving the partial order:

$$x \leq y \Rightarrow f(x) \leq f(y).$$

Such a function is called a **monotone function**.

It is not difficult to see that for any two poset A, B , there exists a natural partial order on the hom-set $\text{Hom}(A, B)$ making it to be a poset and thus proving the 2-morphisms between monotone functions.

Recall that a **thin** category is a category whose every hom-set is a singleton. It is not difficult to verify that a *proset*, viewed as a category (follow Example 1.2.2), is just a thin category.

Since every poset is also a proset, then **Pos** is a sub-2-category of the 2-category of prosets, **Proset**. But moreover, we have

Proposition 5.1.13. *Any proset is equivalent to a poset.*

This is a special case of the theorem that every category has a skeleton.

Negation

Negation is the logic duality.

In the context of relations, the **negation** $\not\sim$ of a binary relation \sim on A is just the complement in the universal relation $A \times A$. In **Rel**, we denote the negation of a relation $R: A \rightarrow A$ by $\neg R$ or R^c .

Now we consider the negation of the conceptions in previous.

Definition 5.1.14. A **comparison** on a set A is a binary relation \sim on A such that in every pair of related elements, any other element is related to one of the original elements in the same order as the original pair:

$$\forall(x, y, z \in A), x \sim z \Rightarrow x \sim y \vee y \sim z$$

Comparison is the negation of transitivity, that means a binary relation \sim on A is a comparison if and only if $\not\sim$ is transitive.

Definition 5.1.15. An **apartness relation** on a set A is a comparison \sim on A that is irreflexive and symmetric.

Apertness relation is the negation of equivalence relation.

Definition 5.1.16. A binary relation \sim on a set A is **connected** if any two elements that are related in neither order are equal. In other word, $\not\sim$ is antisymmetric.

In **Rel**, a relation $R: A \rightarrow A$ is connected if and only if its union with its reverse and the diagonal is the universal relation:

$$R^{\text{op}} \cup R \cup 1_A = A \times A$$

The negation of total order is

Definition 5.1.17. A **linear order** on a set S is a irreflexive, asymmetric, transitive and connected comparison. A **linearly ordered set**, or **loset**, is a set equipped with a linear order.

Operations on a proset

As a special kind of category, we can consider some classical categorical concepts on a proset A .

- A **bottom** \perp of A is just the initial object in A .
- A **top** \top of A is just the terminal object in A .

Remark. Since a poset is a skeletal category, the top and bottom in a poset is thus unique.

- A **lower bound** of a subset B of A is just a cone over elements in B .
- A **upper bound** of a subset B of A is just a cocone under elements in B .

A proset with a top element and a bottom element is called **bounded**. This is different from the notion of a subset B of a proset A to be **bounded**, which means B has both a lower bound and an upper bound.

More generally, A proset is **bounded above** if it has a top element and **bounded below** if it has a bottom element.

- The **meet** $x \wedge y$ of two elements $x, y \in A$ is just their product in A .
- The **infimum** $\inf_{i \in I} x_i$ of a family of elements $\{x_i\}_{i \in I}$ of A is just their product in A .

Remark. It may be more common to use “meet” for a meet of finitely many elements and “infimum” for a meet of (possibly) infinitely many elements, but they are the same concept. The meet may also be called the **minimum** if it equals one of the original elements.

- The **join** $x \vee y$ of two elements $x, y \in A$ is just their coproduct in A .
- The **supremum** $\sup_{i \in I} x_i$ of a family of elements $\{x_i\}_{i \in I}$ of A is just their coproduct in A .

Remark. It may be more common to use “join” for a join of finitely many elements and “supremum” for a join of (possibly) infinitely many elements, but they are the same concept. The join may also be called the **maximum** if it equals one of the original elements.

Since for any two elements in a poset, there can not be more than one morphism between them, thus by Theorem 2.8.3 and its dual, a poset is complete (resp. cocomplete) as a category if and only if it has all infima (resp. suprema). Since we often consider posets, we call a poset satisfying such property an **inflattice** (resp. **suplattice**). Likewise, a **meet-semilattice** is a poset having all finitely meets, a **join-semilattice** is a poset having all finitely joins.

- A **directed set** is a poset which is a filtered category.

Exercises

5.1. Check the “if and only if” statements in text and prove the rest propositions.

5.2. Given two poset A, B , find a natural partial order on the hom-set $\text{Hom}(A, B)$ making it to be a poset.

5.3. Point out that the **extensional property** which states that any two elements in a poset having the same lower bounds are equal is actually a special case of the Yoneda Lemma’s corollary 1.10.4. [Hint: What is $\Upsilon(x)$ for an element x of a poset A ?]

§5.2 Subsets of a proset

For (X, \leq) a proset, a subset A of X is then again a proset whose preorder is the restriction of \leq on A . In other word, there exists a canonical way to make a subset of a proset be a full subcategory of it. Thus when we say a subset of a proset, we actually mean a full subcategory of it.

Among subsets of a proset, a special kind is noteworthy, that is chains.

Definition 5.2.1. A **chain** of a proset is a subset that itself is a toset.

This notion plays a critical role in Zorn's lemma and thus the theory of Noetherianess.

Another important kind of subsets are intervals.

Definition 5.2.2. Given a proset (X, \leq) and an elements x of X .

- The **upwards unbounded interval** $[x, +\infty)$ is the subset

$$\{y \in X \mid x \leq y\}$$

It is also called the **up set** of x , and denoted by $x \uparrow$.

- The **downwards unbounded interval** $(-\infty, x]$ is the subset

$$\{y \in X \mid y \leq x\}$$

It is also called the **down set** of x , and denoted by $x \downarrow$.

Given another element y of X , the **bounded interval** $[x, y]$ is the subset

$$\{z \in X \mid x \leq z \leq y\}$$

Moreover, besides the **closed intervals** above, we also have the **open intervals**

- $(x, +\infty) := [x, +\infty) \setminus \{x\} = \{y \in X \mid x < y\},$
- $(-\infty, x) := (-\infty, x] \setminus \{x\} = \{y \in X \mid y < x\},$
- $(x, y) := [x, y] \setminus \{x, y\} = \{z \in X \mid x < z < y\},$

as well as the **half-open intervals**

- $[x, y) := [x, y] \setminus \{y\} = \{z \in X \mid x \leq z < y\},$
- $(x, y] := [x, y] \setminus \{x\} = \{z \in X \mid x < z \leq y\}.$

It is obvious that, as categories, the up set $x \uparrow$ is isomorphic to the slide category X/x , the down set $x \downarrow$ is isomorphic to the coslide category x/X .

Definition 5.2.3. In a proset X , an **upper set** U is a subset satisfying

whenever $x \leq y$ and $x \in U$, then $y \in U$.

while a **lower set** L is a subset satisfying

whenever $y \leq x$ and $x \in L$, then $y \in L$.

Given a subset A of X , the upper set *generated* by A is

$$A \uparrow := \{y \in X \mid \exists x \in A \text{ s.t. } x \leq y\}$$

while the lower set *generated* by B is

$$A \downarrow := \{y \in X \mid \exists x \in A \text{ s.t. } y \leq x\}$$

Obviously, $A \uparrow = \bigcup_{x \in A} x \uparrow$, $A \downarrow = \bigcup_{x \in A} x \downarrow$.

Alexandroff topology

The Alexandroff topology, is a natural structure of a topological space induced on the underlying set of a proset. Spaces with this topology, called Alexandroff spaces and named after Paul Alexandroff (Pavel Aleksandrov), should not be confused with Alexandrov spaces (which arise in differential geometry and are named after Alexander Alexandrov).

Definition 5.2.4. Given a proset X . Declare subset U of X to be an open subset if it is an upper set. This defines a topology on X , called the **specialization topology** or **Alexandroff topology**.

Proposition 5.2.5. A proset X is a poset if and only if its Alexandroff topology is T_0 .

§5.3 Lattices

Recall that a meet-semilattice is a poset having all finitely meets, a join-semilattice is a poset having all finitely joins. It is not difficult to find that to say a poset is a meet-semilattice is the same to say its opposite is a join-semilattice. Thus, a meet-semilattice is often called a **semilattice** for brevity.

A **semilattice homomorphism** f from a semilattice A to a semilattice B is a function from A to B that preserves finitely meets, view f as a functor, this equals to say that f is continuous.

Semilattices and semilattice homomorphisms form a concrete category **SemiLat**.

Definition 5.3.1. A poset that is both a meet-semilattice and join-semilattice is called a **lattice**.

A **lattice homomorphism** f from a lattice A to a lattice B is a function from A to B that preserves finitely meets and joins, view f as a functor, this equals to say that f is continuous and cocontinuous.

Lattices and lattice homomorphisms form a concrete category **Lat**.

Definition 5.3.2. A poset that is both a inflattice and suplattice is called a **complete lattice**.

Remark. By the adjoint functor theorem for posets, having either all infima or all suprema is sufficient for the other. However, a inflattice morphism may preserve only infima, while dually an suplattice morphism may preserve only suprema.

There are concepts of inflattice homomorphisms, suplattice homomorphisms and complete homomorphisms, which can be defined analogously.

Complete lattices and complete lattice homomorphisms form a concrete category **CompLat**.

§A.1 The fundamental axiom system

What should a set be?

It is common to use foundations of mathematics in which “set” is an undefined term; this is set theory as a foundation. In a pure material set theory like ZFC, every object is a set. Even in a structural approach such as ETCS, it is common for every object to be a structured set in some way or another.

Material set theory conflates two notions of sets, which were elegantly (but not first) described by Mathieu Dupont in a blog post as “set¹” and “set²”, which we will here call “abstract set” and “concrete set”. In the latter case (set²), we have some fixed universe of discourse (for example, collection of all real numbers), and a **concrete set** is a set of elements of this universe (in our example, a set of real numbers). In the former case (set¹), an **abstract set** is a purely abstract concept, an unstructured (except perhaps for the equality relation) collection of unlabelled elements. Arguably (this argument goes back at least to Lawvere), Cantor’s original concept of cardinal number (Kardinalzahl) was the abstraction from a concrete set to its underlying abstract set.

ZFC

The commonly accepted standard foundation of mathematics today is a material set theory, **ZFC** or *Zermelo-Fraenkel set theory with the axiom of choice*.

Axiom (Extensionality). If two sets have the same members, then they are equal and themselves members of the same sets.

Axiom (Specification). Given any set X and any property P of the elements of X , there is a set $\{x \in X \mid P(x)\}$ consisting precisely of those elements of X for which P holds.

Axiom (Empty set). There is an **empty set**: a set \emptyset with no elements.

Axiom (Union). If S is a set, then there is a set $\bigcup S$, **the union of S** , whose elements are precisely the elements of the elements of S .

Axiom (Pairing). If A and B are sets, then there is a set $\{A, B\}$, **the unordered pairing of A and B** , whose elements are precisely A and B .

Axiom (Power set). If X is a set, then there is a set $\mathcal{P}(X)$, **the power set of X** , whose elements are precisely **the subsets of X** , that is the sets whose elements are all elements of X .

Definition A.1.1. The union of a set X and its singleton $\{X\}$ is called the **successor** of X . An inductive set N is a set such that whenever any x is a member of N , its successor is also a member of N .

Axiom (Infinity). Nonempty inductive set exists.

Axiom (Replacement). Given a property $\psi[x, Y]$ with the chosen free variables shown, if X is a set and if for every x in X there is a unique Y (denoted by $\Psi(x)$) such that $\psi[x, Y]$ holds, then there is set $\{\Psi(x) \mid x \in X\}$, **the image of X under ψ** .

Axiom (Choice). If X is a set, each of whose elements has an element, then there is a set with exactly one element from each element of X .

If we abandon the axiom of choice, then the rest axioms form a weaker system called **ZF**, *the Zermelo-Fraenkel set theory*.

For more detail, see *Wikipedia* or any textbook on set theory.

Universe

Definition A.1.2. A **Grothendieck universe** \mathcal{U} is a set \mathcal{U} such that:

1. If x is an element of \mathcal{U} and if y is an element of x , then y is also an element of \mathcal{U} .
2. If x is an element of \mathcal{U} , then $\mathcal{P}(x)$, the power set of x , is also an element of \mathcal{U} .
3. If $\{x_i\}_{i \in I}$ is a family of elements of \mathcal{U} , and if I is an element of \mathcal{U} , then the union $\bigcup_{i \in I} x_i$ is an element of \mathcal{U} .
4. $\mathbb{N} \in \mathcal{U}$.

Elements of a Grothendieck universe \mathcal{U} are called \mathcal{U} –**small sets**, while a subset of \mathcal{U} is called \mathcal{U} –**moderate**. If the universe \mathcal{U} is understood, we may simply say **small** and **moderate**.

We now prove a useful lemma for a given Grothendieck universe \mathcal{U} .

Lemma A.1.3. *If $x \in \mathcal{U}$ and $y \subseteq x$, then $y \in \mathcal{U}$.*

Proof. $y \in \mathcal{P}(x)$ because $y \subseteq x$. $\mathcal{P}(x) \in \mathcal{U}$ because $x \in \mathcal{U}$, so $y \in \mathcal{U}$. □

If \mathcal{U} is a Grothendieck universe, then it is easy to show that \mathcal{U} is itself a model of ZFC. Therefore, one cannot prove in ZFC the existence of a Grothendieck universe, and so we need extra set-theoretic axioms to ensure that uncountable universes exist. Grothendieck’s original proposal was to add the following axiom of universes to the usual axioms of set theory:

Axiom (Universes). Every set belongs to a universe.

Whenever any operation leads one outside of a given Grothendieck universe, there is guaranteed to be a bigger Grothendieck universe in which one lands. In other words, every set can be small if your universe is large enough!

Later, Mac Lane pointed out that often, it suffices to assume the existence of one uncountable universe. In particular, any discussion of “small” and “large” that can be stated in terms of sets and proper classes can also be stated in terms of a single universe \mathcal{U} .

Other axiom system

There are other material set theories, such as NBG, *the Von Neumann-Bernays-Gödel set theory*, MK, *the Morse-Kelley set theory* and so on.

Unlike **material** set theories, A **structural** set theory is a set theory which describes structural mathematics, and only structural mathematics. As conceived by the structuralist, mathematics is the study of structures whose form is independent of the particular attributes of the things that make them up.

For example, the structuralist says, essentially, that the number “3” should denote “the third place in a natural numbers object” rather than

some particular set such as $\{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}$ as it does in any definition of “the set of natural numbers” in ZF.

Among category theorists, it’s popular to state the axioms of a structural set theory by specifying elementary properties of the category of sets. For this reason structural set theory is often called **categorical** set theory.

The original, and most commonly cited, categorially presented structural set theory is Bill Lawvere’s **ETCS**. It is weaker than ZFC and must be supplemented with an axiom of collection to handle some esoteric parts of modern mathematics, although it suffices for most everyday uses.

Another structural set theory, which is stronger than ETCS (since it includes the axiom of collection by default) and also less closely tied to category theory, is **SEAR**.

Exercises

A.1. Show that any Grothendieck universe \mathcal{U} contains:

- All singletons of each of its elements,
- All products of all families of elements of \mathcal{U} indexed by an element of \mathcal{U} ,
- All disjoint unions of all families of elements of \mathcal{U} indexed by an element of \mathcal{U} ,
- All intersections of all families of elements of \mathcal{U} indexed by an element of \mathcal{U} ,
- All functions between any two elements of \mathcal{U} ,
- All subsets of \mathcal{U} whose cardinal is an element of \mathcal{U} .

§A.2 Axiom of choice

In the viewpoint of category theory, the axiom of choice (**AC**) is the following statement:

Axiom (AC). Every surjection in the category **Set** splits.

In this section, we introduce some equivalence statements of AC under the assumption ZF. The most important among them are Zorn's lemma and the well-ordering theorem.

Here is a very short list from *nLab*; much longer lists can be found elsewhere, such as at *Wikipedia*. Some of the statements on this list, though, may be of interest to *nLabbers* but are not commonly mentioned as equivalents of choice.

- The well-ordering theorem.
- Zorn's lemma,
- That (L= monomorphisms, R= epimorphisms) is a weak factorization system on **Set**.
- That **Set** is equivalent to its own free exact completion.
- That there exists a group structure on every inhabited set (see *this MO answer*).
- That every fully faithful and essentially surjective functor between strict categories is a strong equivalence of categories.
- That the nonabelian cohomology $H^1(X; G)$ is trivial for every discrete set X and every group G (see *this post*).

Zorn's lemma

Theorem A.2.1 (Zorn's lemma). *Each proset S has a maximal element if every chain in S has an upper bound.*

A sketch of proof can be found in *nLab*.

The well-ordering theorem

Definition A.2.2. A **well-order** \leq on a set S is a total order that is **well-founded**, that means, every nonempty subset of S has a minimal element. A set equipped with a well-order is called a **well-ordered set**, or a **woset**.

This notion is sometimes very useful since it allows us to extend mathematical induction to any well-ordered sets.

Proposition A.2.3. *Let $P(x)$ be a statement for elements of a woset S whose strict order is denoted by $<$. Then, to show $P(x)$ holds for all elements x of S , it suffices to show that $P(x_0)$ holds for the minimal element x_0 in S , and that*

If x is an element of S and $P(y)$ is true for all y such that $y < x$, then $P(x)$ must also be true.

Theorem A.2.4 (The well-ordering theorem). *Given any set S , there exists a well-order \leq on S .*

A sketch of proof can be found in *Wikipedia* and *nLab*

§A.3 Ordinals and cardinals

Naively, a **cardinal number** should be an isomorphism class of sets, and the **cardinality** of a set S would be its isomorphism class. That is:

1. every set has a unique cardinal number as its cardinality;
2. every cardinal number is the cardinality of some set;
3. two sets have the same cardinality if and only if they are isomorphic as sets.

Then a **finite cardinal** is the cardinality of a finite set, while an **infinite cardinal** or **transfinite cardinal** is the cardinality of an infinite set.

Formally, instead of define what is a cardinal number, we define the category of cardinal numbers **Card** as the skeleton of **Set**.

Naively, a **ordinal number** should be an isomorphism class of wosets, and the **ordinal rank** of a woset (S, \leq) would be its isomorphism class. That is:

1. every woset has a unique ordinal number as its ordinal rank;
2. every ordinal number is the ordinal rank of some woset;
3. two wosets have the same ordinal rank if and only if they are isomorphic as wosets.

Then a **finite ordinal** is the ordinal rank of a finite woset, while an **infinite ordinal** or **transfinite ordinal** is the ordinal rank of an infinite woset.

Formally, instead of define what is a ordinal number, we define the category of ordinal numbers **Ord** as the skeleton of **Wos**, the category of wosets.

Cardinal arithmetic

As a skeleton of **Set**, the operations on **Set** define the natural arithmetic operations on **Card**.

More explicitly, denote the cardinality of a set S by $|S|$, we have

- $\sum_i |S_i| = |\bigsqcup_i S_i|$;

- $\prod_i |S_i| = |\prod_i S_i|$;
- $|Y|^{|X|} = |\operatorname{Hom}(X, Y)|$;

§A.4 The category of sets

Cap.B Famous Books

Here is a list of some famous books in present. The articles discuss them are copied from *nLab*.

§B.1 Handbook of Analysis and its Foundations	177
§B.2 Elephant	180

§B.1 Handbook of Analysis and its Foundations

Erich Schechter's *Handbook of Analysis and its Foundations* is a large book, intended for self study by beginning graduate students or senior-level undergraduates, on all of the basic topics of abstract analysis and then some. Its logical flow is very much like that of Bourbaki, but focussed on that which applies to analysis and written in a modern style. Except for the slightly broken index (check the **errata!**), it is very user-friendly, with sketched proofs phrased as exercises with hints, many examples (eventually), and abundant cross references. It is also extremely self contained; the only prerequisite is mathematical maturity, and the first section even helps with that!

It begins, as the name implies, with foundations: not only the usual naïve set theory, but also a discussion of ZFC, constructive mathematics, and enough model theory to do nonstandard analysis. There is special emphasis on the axiom of choice; throughout the book, it is explicitly pointed out whenever anything beyond dependent choice and excluded middle is required. (The axioms of replacement and foundation, on the few occasions when they appear, are also pointed out, so logically the book takes place in $Z^- + DC$.)

The book then moves on to algebra, moving from monoids to fields, on the grounds that such algebra also serves as a foundation for analysis. This culminates in a treatment of category theory; this is somewhat unsatisfactory (although very good for an analysis book!) and is not much more than Bourbaki's theory of structures reinterpreted as a theory of concrete categories. After algebra comes topology, and then analysis proper.

Those aspects of analysis that do not depend on the theory of the real numbers are also covered when appropriate in the set-theory and algebra sections of the book; thus topological spaces and convex sets (for example) are defined early, although they are not thoroughly studied until later (after the foundational parts are finished). The analysis in the book is soft and abstract, on the grounds that this material serves as the proper foundation for hard results in concrete cases. However, many concrete examples are given to illustrate the abstract ideas. The breadth of topics covered, even

within analysis itself, is quite wide; from convergence spaces to ultrabarrels, from the Henstock integral to the Brouwer fixed-point theorem, it has it all.

But everything must stop somewhere; it does not cover **complex analysis**.

Contents

- Part A: Sets and Orderings (Chapters 1–7)
- Part B: Algebra (Chapters 8–14)
- Part C: Topology and Uniformity (Chapters 15–21)
- Part D: Topological Vector Spaces (Chapters 22–30)

1. Sets
2. Functions
3. Relations and Orderings
4. More About Sups and Infs
5. Filters, Topologies, and Other Sets of Sets
6. Constructivism and Choice
7. Nets and Convergences
8. Elementary Algebraic Systems

28. Duality and Weak Compactness
29. Vector Measures
30. Initial Value Problems

§B.2 Elephant

The Elephant is a book on topos theory by Peter Johnstone.

The full title is *Sketches of an Elephant: A Topos Theory Compendium*. Like *Gravitation*, the title can be taken to refer not only to the subject matter but also to the immense size and scope of the book itself. Like *The Lord of the Rings*, it consists of 6 parts arranged evenly into 3 volumes (but without appendices). Actually, Volume 3 has not yet been published (so who knows? it may have appendices after all!).

The Elephant is a good reference for anything related to topos theory, and we may often cite it here. However, it introduced many terminological changes, some of which may not be widely accepted or even known. (Fortunately, it will tell you about these in the text.)

Contents

A Toposes as Categories

A1 Regular and cartesian closed categories

A1.1 Preliminary assumptions

A1.2 Cartesian categories

A1.3 Regular categories

A1.4 Coherent categories

A1.5 Cartesian closed categories

A1.6 Subobject classifiers

A2 Toposes - basic theory

A2.1 Definition and examples

A2.2 The monadicity theorem

A2.3 The Fundamental Theorem

A2.4 Effectiveness, positivity and partial maps

A2.5 Natural number objects

A2.6 Quasitoposes

A3 Allegories

- A3.1 Relations in regular categories
 - A3.2 Allegories and tabulations
 - A3.3 Splitting symmetric idempotents
 - A3.4 Division allegories and power allegories
- A4 Geometric morphisms - basic theory
 - A4.1 Definition and examples
- B 2-Categorical Aspects of Topos Theory
 - B1 Indexed categories and fibrations
 - B1.1 Review of 2-categories
 - B1.2 Indexed categories
 - B1.3 Fibrations
 - B1.4 Limits and colimits
 - B1.5 Descent conditions and stacks
 - B2 Internal and locally internal categories
 - B2.1 Review of enriched categories
 - B2.2 Locally internal categories
 - B2.3 Internal categories and diagram categories
 - B2.4 The indexed adjoint functor theorem
 - B2.5 Discrete opfibrations
 - B2.6 Filtered colimits
 - B2.7 Internal profunctors
 - B3 Toposes over a base
 - B3.1 S -Toposes as S -indexed categories
 - B3.2 Diaconescu's theorem
 - B3.3 Giraud's theorem
 - B3.4 Colimits in \mathbf{Top}
- C Toposes as Spaces
 - C1 Sheaves on a locale

- C1.1 Frames and nuclei
 - C1.2 Locales and spaces
 - C1.3 Sheaves, local homeomorphisms and frame-valued sets
 - C1.4 Continuous maps
 - C1.5 Some topological properties of toposes
- C2 Sheaves on a site
 - C2.1 Sites and coverages
 - C2.2 The topos of sheaves
 - C2.3 Morphisms of sites
 - C2.4 Internal sites and pullbacks
 - C2.5 Fibrations of sites
- C3 Classes of geometric morphisms
 - C3.1 Proper maps
 - C3.2 Locally connected morphisms
 - C3.3 Atomic morphisms
 - C3.4 Local maps
- D Toposes as theories
 - D1 First-order categorical logic
 - D1.1 First-order languages
 - D1.2 Categorical semantics
 - D1.3 First-order logic
 - D1.4 Syntactic categories
 - D1.5 Classical completeness
 - D2 Sketches
 - D2.1 The concept of sketch
 - D2.2 Sketches and theories
 - D2.3 Sketchable and accessible categories
 - D2.4 Properties of model categories
 - D3 Classifying toposes

- D3.1 Classifying toposes via syntactic sites
 - D3.2 The object classifier
 - D3.3 Coherent toposes
- D4 Higher-order logic
 - D4.1 Predicative type theories
 - D4.2 Axioms of choice and Booleanness
 - D4.3 Real numbers in a topos
- D5 Aspects of finiteness
 - D5.1 Finite cardinals
 - D5.2 Finitary algebraic theories
 - D5.3 Kuratowski-finiteness
- E Homotopy and Cohomology
 - E1 Homotopy theory for toposes
 - E1.1 Homotopy theory of toposes
 - E1.2 The fundamental groupoid via paths
 - E1.3 The fundamental groupoid via coverings
 - E1.4 Natural homotopy
 - E2 Algebraic homotopy theory
 - E2.1 Quillen model structures
 - E2.2 Model structure for simplicial sets
 - E2.3 Model structures for sheaves
 - E3 Cohomology theory
 - E3.1 Abelian groups and modules in a topos
 - E3.2 Čech cohomology
 - E3.3 Torsors and non-abelian cohomology
 - E3.4 Cohomological applications of descent theory
- F Toposes as Mathematical Universes
 - F1 Synthetic differential geometry

- F1.1 Properties of the generic ring
- F1.2 Rings of line type
- F1.3 Well-adapted models
- F1.4 Tiny objects
- F1.5 Synthetic integration theory
- F1.6 Intrinsic infinitesimal
- F2 Topos theory and set theory
 - F2.1 Internal sets in a topos
 - F2.2 Algebraic set theory
 - F2.3 Independence proofs via classifying toposes
 - F2.4 Independence of the axiom of choice

Symbols

$(S \downarrow T)$ *comma category.* 1.8

$(S \downarrow t)$ *the category of S -costructured arrows with codomain t in.* 1.8

$(s \downarrow T)$ *the category of T -structured arrows with domain s in.* 1.8

$1_A, \Delta_A$ *the equality on A .* A.2

$1_A, \text{id}_A$ *the identity of A .* 1.1

$A \amalg_C B$ *amalgam.* 2.6

$A \approx B$ *isomorphic.* 1.3

$A \equiv B, A \simeq B$ *equivalent.* 1.6

$A \times_C B$ *fibre product.* 2.6

F^{op} *the opposite functor of F .* 1.5

$I/\mathcal{C}, (I \downarrow \mathcal{C})$ *the co-slice category under I .* 1.2

$L \dashv R$ *adjunction.* 3.1

$[\mathcal{A}, \mathcal{B}], \mathcal{B}^{\mathcal{A}}$ *the functor category from \mathcal{A} to \mathcal{B} .* 1.4

$\langle f, g \rangle$ *cone-morphism to a product.* 2.4

$\mathcal{C}/I, (\mathcal{C} \downarrow I)$ *the slice category over I .* 1.2

\mathcal{C}^{op} *the opposite category of \mathcal{C} .* 1.2

$\mathcal{C}^{\rightarrow}$ *the arrow category of \mathcal{C} .* 1.2

$\text{Cograph}(f), X \star^f Y$ *cograph of f* . 3.1
 Δ *the diagonal functor*. 1.5
 Δ_B *the constant/selection functor to B* . 1.5
 $\Delta_{\mathcal{A}}$ *the constant/selection functor from \mathcal{A} to $\mathbf{1}$* . 1.8
 Γ_f *graph of f* . 2.4
 $\text{Graph}(f), X \times_f Y$ *graph of f* . 3.1
 $\mathbf{I}_{\mathcal{C}}$ *the identity functor of \mathcal{C}* . 1.5
 $\text{Lan}_p F$ *left Kan extension of F along p* . 3.4
 \mathcal{P} *the power-set functor*. 1.5
 \mathcal{Q} *the contravariant power-set functor*. 1.5
 $\text{Ran}_p F$ *right Kan extension of F along p* . 3.4
 Υ *Yoneda embedding*. 1.10
 $\beta * \alpha$ *the Godement product*. 1.4
 $\text{coker}(f, g)$ *coequalizer*. 2.5
 $\coprod_{i \in I} A_i$ *coproduct*. 2.4
 $\varinjlim D, \varinjlim_i D_i$ *colimit*. 2.3
 $\varprojlim D, \varprojlim_i D_i$ *limit*. 2.3
 $\ker(f, g)$ *equalizer*. 2.5
 $\mathbf{1}$ *the terminal/trivial category*. 1.2
 $\prod_{i \in I} A_i$ *product*. 2.4
 f^* *pull back through f* . 1.5
 f_* *push forward through f* . 1.5

$\text{Hom}(A, B), \text{Hom}_{\mathcal{C}}(A, B)$ *the hom-collection.* 1.1

$\text{Nat}(A, B)$ *the collection of natural transformations.* 1.10

$A \Rightarrow B$ *a natural transformation from A to B .* 1.4

Categories

Ban_∞ *real Banach spaces and bounded linear mappings.* 1.2

Ban *real Banach spaces and linear contractions.* 1.2

CAT *the “very large” category of categories and functors.* 1.1, 1.6, 1.7

Cat *small categories and functors.* 1.1, 1.2, 1.6, 1.7, 1.11, 2.2, 2.4, 15.4

Co – cone(*D*) *co-cones under *D*.* 2.1, 2.3

Cone(*D*) *cones over *D*.* 2.1, 2.3, 2.8, 2.11, 2.12

Diff *differentiable manifolds and smooth mappings.* 1.2

DivAb *divisible abelian groups and group homomorphisms.* 1.3

Elts(*F*) *elements of *F*.* 1.8, 2.13, 2.14, 3.1

FinVect_{*k*} *finite-dimensional vector spaces and linear mappings over a field *k*.* 1.4, 1.6

Grp *groups and group homomorphisms.* 1.2–1.5

Mat *matrices.* 1.2, 1.6

Met_{*k*} *metric spaces and metric mappings over a field *k*.* 1.2

Mod_{*R*} *right *R*–modules and module homomorphisms.* 1.2, 1.3

PSh(*C*) *presheaves on *C*.* 1.5, 1.10, 1.11, 2.13, 3.1

Ring *rings and ring homomorphisms.* 1.2, 1.3

Rel *2-category of relations.* A.2

Set *sets and functions.* 0.0, 1.2–1.6, 1.8, 1.10, 2.0, 2.2–2.8, 2.10–2.14, 3.1, 3.2, 3.4

Top *topological spaces and continuous mappings.* 1.2, 1.3, 2.2

Uni *uniform spaces and uniformly continuous functions.* 1.2

Vect_k *vector spaces and linear mappings over a field k .* 1.2
